ABSTRACT

POPLIN, PHILLIP L.. The Semiring of Multisets. (Under the direction of Professor R. Hartwig.)

The aim of this paper is to develop the basic theory of the Multiset Algebra. Multisets provide a connection between the eigenvalue/eigenvector equations for the Max-Plus and nonnegative real number systems. Multisets provide a more general setting than either of these two algebras. Results about these two algebras will be developed from the theory of Multisets.
THE SEMIRING OF MULTISETS

BIOGRAPHY

Phillip Poplin received his A.S. degree from Gaston College, B.S. degree from the University of North Carolina at Charlotte, and M.A. degree from Appalachian State University. Phillip began pursuing his Ph.D. degree in Mathematics at North Carolina State University in January 1992. While studying at NCSU Phillip worked as an instructor at Wake Technical Community College and also as a Teaching Assistant at NCSU. Phillip has spent his summers working at outdoor backpacking camps for youth. His other interests include chess, working with computers, and, of course, teaching and studying mathematics.
ACKNOWLEDGEMENTS

I would like to thank my advisor, Robert Hartwig, for his encouragement in the preparation of this thesis. I would like to thank him for his support, guidance, and friendship throughout my studies at North Carolina State University.

1 Introduction and Motivation

The Max-Plus algebra is one example of the class of Path Algebras. Path algebras have evolved over the past few decades to help answer questions that arise in weighted graph theory. At first several different Path Algebras were investigated separately but as research evolved it was found that the same theory held for all Path Algebras. This was the beginning of the field of idempotent semirings, which is a subclass of semirings. This theory covers areas of path algebras as well as lattices and weighted graph theory.

The use of the Max-Plus (max,+) algebra has allowed many problems which are non-linear in the usual algebra system to be linearized. This has allowed difficult problems to be solved by elementary methods. The (max,+) algebra system has evolved to solve a multitude of problems in seemingly different fields of study. As such the (max,+) algebra has been used in Discrete Event Systems, transportation networks, parallel computations, project management, machine scheduling, and many other fields. For a detailed introduction we refer to [13].

Semirings provide the global setting of the present thesis. Within this context we study some matrix identities which can be developed analogously from the theory of rings. In particular we show that some identities in a ring can be generalized to an analogous identity in a semiring. We begin with an introduction to semirings. The semirings we study can be separated into three special types; idempotent semirings (which are Path Algebras), zerouniform semirings, and cancellative semirings. The Max-Plus and Max-Times Algebras are subclasses of the class of Path Algebras.

As we will see in Example 5.1 the Max-Plus Algebra system can be used to solve problems of discrete event systems using linear algebra. One aim of this thesis is to obtain a better understanding of the relative relationship between the Max-Plus, Max-Times, Multiset, and Nonnegative number systems. Indeed we show that \( \mathbb{R}^+ \), \( \mathbb{R}^* \), and the nonnegative reals numbers can all be viewed as a special case of multisets. We give an overview of the Max-Plus Algebra, including many of the theorems used in connection with these problems. The Max-Times Algebra is isomorphic to the Max-Plus Algebra system, but since it is closer to the usual algebra, it is somewhat easier to develop. The \( \mathbb{R}^+ \) algebra is more natural for applications but \( \mathbb{R}^* \) is easier to use. We survey the material known about these systems and add several new results.

A search for a common enveloping theory between the Max-Times algebra and the non-negative real number system leads to the semiring of multisets, and, subsequently, to its ring of differences. The Multiset Algebra will allow us to recover all the cases above by performing suitable elementwise computations.

The multiset algebra is developed. We give a detailed introduction to multisets, then proceed to equations with multisets and systems of equations involving multisets. We study the multiset algebra system and its relationship to the other algebras. The multiset algebra allows us to keep an optimal amount of information throughout the calculations. Keeping more information, however,
also has disadvantages in that some problems become much more complicated. We show how multi-
sets allow us to connect the eigenvalue/eigenvector equations for the Max-Times algebra with that of our conventional algebra system. Figure 1 shows the interconnectedness of these structures.
2 Semirings

A semiring is one of the fundamental structures in mathematics. The set most people first encounter is the natural numbers, which is a semiring, as is the nonnegative real numbers. Since a semiring is a more general structure than the familiar ring structure, the theory is less developed and more fractured in its development.

2.1 Axioms

We begin with a definition of the semiring structure

Definition 2.1. A semiring is a set $R$, equipped with two binary operations, $+$ and $\times$, which have the following properties.

1. The $+$ operation is commutative and associative.
   
   (a) $a + b = b + a$ for all $a, b \in R$
   
   (b) $(a + b) + c = a + (b + c)$ for all $a, b, c \in R$

2. The $\times$ operation is associative and distributive over $+$.

   (a) $(a \times b) \times c = a \times (b \times c)$ for all $a, b, c \in R$
   
   (b) $a \times (b + c) = (a \times b) + (a \times c)$ for all $a, b, c \in R$
   
   (c) $(b + c) \times a = (b \times a) + (c \times a)$ for all $a, b, c \in R$

3. The set $R$ contains a zero element $\theta$ such that:

   (a) $\theta + a = a$ for all $a \in R$
   
   (b) $\theta \times a = a \times \theta = \theta$ for all $a \in R$ (absorption)

4. The set $R$ contains a unit element $e$ such that

   $e \times a = a \times e = a$ for all $a \in R$

   The zero element is absorbing, which has now become an axiom instead of a theorem. The above axioms define a semiring. If $e = \theta$ then $r = re = r\theta = 0$ for all $r$ in $R$, so $R = \{\theta\}$. We add the following axiom to avoid this trivial case.

5. $e \neq \theta$

   We add further axioms to define specific types of semirings.

Definition 2.2. A commutative semiring is a semiring, $R$, with the additional axiom:

6. $a \times b = b \times a$ for all $a, b \in R$
Definition 2.3. An **additively idempotent semiring** has the additional axiom:

7. $a + a = a$ for all $a \in R$

Although one could also define a semiring which is multiplicatively idempotent, we will have no need for this definition in the present setting. As such we will refer to an idempotent semiring as meaning additively idempotent.

Definition 2.4. A **cancellative semiring**, $R$, satisfies the additional axiom:

8. If $a + b = a + c$ then $b = c$ for all $a, b, c \in R$

Definition 2.5. A **zerosumfree semiring**, $R$, satisfies the additional axiom:

9. If $a + b = \theta$ then $a = b = \theta$.

Definition 2.6. A **semifield** is a semiring in which the nonzero elements of $R$ have a multiplicative inverse. It is noted that this definition uses the existence of the multiplicative identity as an axiom of semirings.

If $a \in R$, and $a \neq \theta$, then $a$ is a **zero divisor** in $R$ if there exists a $b \neq \theta$ in $R$ such that $a \times b = \theta$.

Although one could define a left and right zero divisor separately, the semirings in this thesis will be commutative, so the definitions are the same.

We see from the above axioms that the important difference between these semiring structures and that of a ring is the lack of an additive inverse. It is this fact that separates rings and semirings. Any theory that requires the existence of an additive inverse can not be handled by a semiring structure and must be embedded in a ring structure.

If $S$ is a subset of $R$ which is also a semiring, then $S$ is called a subsemiring of $R$.

**Example 2.7.** $(\mathbb{N}, +, \times)$, the natural numbers, with the usual addition and multiplication is a familiar example of a semiring. We also note that $\mathbb{N}$ is a subsemiring of $\mathbb{Q}^+$, the semiring of nonnegative rational numbers, which is a subsemiring of $\mathbb{R}^+$, the semiring of nonnegative real numbers.

### 2.2 Matrices

We let $R_n$ equal the set of all $n \times 1$ vectors with elements from $R$. We also let $R_{n \times n}$ equal the set of all $n \times n$ matrices with elements from $R$.

**Definition 2.8.** Suppose $A, B \in R_{n \times n}$, $a \in R$. The following are the definitions of the basic operations of matrices in the semiring.

1. $I_n \equiv I = \begin{cases} I_{ii} = e & \forall i = 1 \ldots n \\ I_{ij} = \theta & \forall i \neq j \end{cases}$ = Identity matrix in $R_{n \times n}$. 

(2) \((a \times A)_{ij} \equiv \alpha \times a_{ij}\)

(3) \([A + B]_{ij} = a_{ij} + b_{ij}\)

(4) \([A \times B]_{ij} = [\sum_{k=1}^{n} (a_{ik} \cdot b_{kj})]\)

(5) The zero matrix, \(\theta_{n \times n}\), is defined as the matrix with all elements equal to the \(\theta\)-element.

(6) The ones-matrix, \(J_{n \times n}\), is defined as the matrix with all elements equal to the \(e\)-element.

We may omit the "\(\times\)" when it is understood, or we may replace it by the "\(\cdot\)", as the need arises.

**Definition 2.9 (Eigenvalue-Eigenvector Equations).**

Given a matrix \(A\), if \(\lambda \in \mathbb{R}\) and \(\mathbf{x} \in \mathbb{R}^{n}\) exists such that Equation (1) holds, then \(\lambda\) is called an eigenvalue of \(A\) and \(\mathbf{x}\) is called a right eigenvector of \(A\).

\[
A\mathbf{x} = \lambda \mathbf{x} \quad \Rightarrow \quad \begin{bmatrix}
    a_{11} & a_{12} & \cdots & a_{1n} \\
    a_{21} & a_{22} & \cdots & a_{2n} \\
    \vdots & \vdots & \ddots & \vdots \\
    a_{n1} & a_{n2} & \cdots & a_{nn}
\end{bmatrix}
\begin{bmatrix}
    x_1 \\
    x_2 \\
    \vdots \\
    x_n
\end{bmatrix}
= \lambda
\begin{bmatrix}
    x_1 \\
    x_2 \\
    \vdots \\
    x_n
\end{bmatrix}
\]  

\[
\Rightarrow \begin{cases}
    a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = \lambda x_1 \\
    a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n = \lambda x_2 \\
    \vdots \\
    a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n = \lambda x_n
\end{cases}
\]  

**Definition 2.10.** The matrix \(A\) is said to be reducible is there exists a permutation matrix \(P\) such that \(PAP^{-1} = \begin{bmatrix} A_1 & A_2 \\ 0 & A_4 \end{bmatrix}\).

If the matrix \(A\) is not reducible then we say that \(A\) is irreducible.

**Theorem 2.11.** If \(A \neq \theta\) and \(A\) is reducible, then

(a) \(A^k\) is reducible for all \(k\)

(b) \(\sum_{k} A^k\) is reducible.
Proof. Suppose \( A \approx \begin{bmatrix} B & C \\ 0 & D \end{bmatrix} \).

(a) \( A^k \approx \begin{bmatrix} B^k & 0 \\ 0 & D^k \end{bmatrix} \),
and

(b) \( \sum_k A^k \approx \begin{bmatrix} \sum_k B^k & 0 \\ 0 & \sum_k D^k \end{bmatrix} \).

The following Corollary follows immediately from the above theorem.

**Corollary 2.12.** If \( \lambda \geq 0 \), and there exists \( k \) such that \( A^k \) is irreducible, then \( A \) is irreducible.

### 2.3 Graphs

A **weighted directed graph** is a triplet \((V,E,W)\). \( V \) is a set of vertices, called **nodes**. The nodes will be labeled as \( S_i \) or simply as \( i \), where it is unambiguous. \( E \) is the set of edges, or **arcs**, given as a directed line segment from node \( S_i \) to \( S_j \). \( W \) is the set of weights associated with each arc. Since all graphs in this thesis are weighted directed graphs, we simply refer to these as **graphs**.

A path from node \( S_{i_0} \) to \( S_{i_t} \) is a sequence: \((S_{i_0}, S_{i_1}, \ldots, S_{i_t})\), or referred to simply as the sequence: \((i_0, i_1, \ldots, i_t)\). The nodes \( i_k \) are said to be on the path. The path is said to pass through the nodes. The **length** of the path is \( t \). The path is said to be an **elementary path** if the nodes \((i_1,i_2,\ldots,i_t)\) are pairwise distinct. (No repeated nodes.) The length of an elementary path is at most \( t - 1 \). A path is called a **circuit** if \( i_0 = i_t \), and a path is called a **cycle** if it is an **elementary circuit**. A **loop** is a cycle which consists of a single arc. The length of a circuit is the length of its path. Elementary circuits have length of at most \( n \), in a graph with \( n \) nodes. When listing the nodes of a circuit, the first node can be any node on the graph; the other nodes are given in the order around the circuit.

The **adjacency matrix** of a graph is the matrix \( A \) with elements made of the weights of the arcs of the graph.

\[
a_{ij} = \begin{cases} w_{ij} & \text{if an arc exists from node } i \text{ to node } j \\ \theta & \text{otherwise.} \end{cases}
\]

**Definition 2.13.** \( G(B) \) is the graph which has \( B \) has its adjacency matrix. A matrix \( B \), has exactly one graph associated with it, and a graph has a unique adjacency matrix.

We can associate a **path product** to each path \((i_0, i_1, \ldots, i_t)\) as: \( w_{i_0i_1} \times w_{i_1i_2} \times \cdots \times w_{i_{t-1}i_t} \). If \( \tau \) is a path, say \( i_1, i_2, \ldots, i_t \), then we will write

\[
\omega(\tau) = w_{i_0i_1} \times w_{i_1i_2} \times \cdots \times w_{i_{t-1}i_t},
\]

or using the elements of the matrix \( A \) as

\[
\omega(\tau) = a_{i_0i_1} \times a_{i_1i_2} \times \cdots \times a_{i_{t-1}i_t}.
\]

We write \( \ell(\tau) \) for the length of the path \( \tau \).
The following theorems are from linear algebra and carry over analogously to $\mathfrak{M}^+$. 

**Theorem 2.14 (Frobenius Normal Form).**
Suppose $M$ contains $k$ strongly connected components. Then there exists a permutation matrix $P$ such that $M$ takes the following block triangular form:

$$
\overline{M} = P M P^{-1} = \begin{bmatrix}
\overline{M}_1 & \overline{M}_{12} & \cdots & \overline{M}_{1k} \\
0 & \overline{M}_2 & \cdots & \overline{M}_{2k} \\
\vdots & \ddots & \ddots & \ddots \\
0 & \cdots & 0 & \overline{M}_k
\end{bmatrix}
$$

(4)

where $\overline{M}_1, \overline{M}_2, \ldots, \overline{M}_k$ are all irreducible submatrices which correspond to $k$ strongly connected components of $G(\overline{M})$.

**Theorem 2.15 (Refined Frobenius Normal Form).**
Suppose $M$ contains $k$ strongly connected components. Then there exists a permutation matrix $P$ such that $M$ takes the following block triangular form:

$$
\overline{M} = P M P^{-1} = \begin{bmatrix}
\overline{M}_1 & \overline{M}_{12} & \cdots & \overline{M}_{1k} \\
\overline{M}_2 & \overline{M}_2 & \cdots & \cdots \\
\vdots & \ddots & \ddots & \ddots \\
\overline{M}_k & 0 & \cdots & \overline{M}_{k+1}
\end{bmatrix}
$$

(5)

where $\overline{M}_1, \overline{M}_2, \ldots, \overline{M}_k$ are all irreducible submatrices which correspond to $k$ strongly connected components of $G(\overline{M})$.

The following fact shows how elements in the power of a matrix, $A$, are related to the graph associated with $A$.

**Fact 2.16.** The sum of all of all $t$-step path-products from node $S_i$ to node $S_j$ can be represented by:

$$
(B^t)_{ij} = \sum_{k_1} \sum_{k_2} \cdots \sum_{k_{t-1}} b_{i,k_1} b_{k_1,k_2} \cdots b_{k_{t-1},j}
$$

(6)

The proof of the following theorem is graph-theoretically based, and therefore the proof is valid in any semiring.

**Theorem 2.17.** The following are equivalent:
(1) A is reducible.

(2) G(A) has an absorbing class.

(3) G(A) is not strongly connected.

Proof.

(1 $\implies$ 2) Suppose $A \approx B = \begin{bmatrix} S_1 & \cdots & S_r & S_{r+1} & \cdots & S_n \\ \vdots & & \vdots & & \vdots & \vdots \\ S_r & & ? & & ? & \vdots \\ \vdots & & \vdots & & \theta & \vdots \\ S_{r+1} & & ? & & ? & \vdots \\ \vdots & & \vdots & & \vdots & \vdots \\ S_n & & ? & & ? & \vdots \end{bmatrix}$

Let $G = G(B)$.

Let $W = \{S_{r+1}, \ldots, S_n\}$, and let $W^c = \{S_1, \ldots, S_r\}$. Since $(B)_{ij} = \theta$ for $r+1 \leq i \leq n$ and $1 \leq j \leq n$, then no arc exists between $S_i$ and $S_j$. Therefore $W$ is an absorbing class.

(2 $\implies$ 3) Suppose that $B$ has an absorbing class, say $W = \{S_{r+1}, \ldots, S_n\}$. Then $G$ cannot be strongly connected since there is no path from $S_{r+1}$ to $S_1$.

(3 $\implies$ 2) Suppose that $G$ is not strongly connected. Then there exists nodes $S_i$ and $S_j$ such no path exists from $S_i$ to $S_j$. Let $W = \{S_k \mid S_i \rightarrow S_k\}$, and let $W^c = \{S_k \mid S_k \not\in W\}$. We claim that there is no path from $W$ to $W^c$. If such a path exists, then there is a $u \in W$, and $v \in W^c$, with $u \rightarrow v$. Then $S_i \rightarrow u \rightarrow v$, and $S_i \rightarrow v$ and $v \in W$, which is a contradiction. Therefore no path exists from $W$ to $W^c$.

(2 $\implies$ 1) Let $W$ be the set of nodes in the absorbing class. Since there is no path from a node in $W$ to a node in $W^c$ then $B_{ij} = \theta$ if $S_i \in W$ and $S_j \in W^c$. So $B = \begin{bmatrix} B_1 & B_3 \\ 0 & B_4 \end{bmatrix}$.

\[\square\]

Lemma 2.18 is from [9, page 50].

**Lemma 2.18.** If $G$ is a graph with no cycles then the vertices of $G$ can be relabeled so that there is no arc from $S_i$ to $S_j$ if $i < j$.

**Corollary 2.19.** If $A$ is the adjacency matrix associated with the graph $G$ and $G$ has no cycles

\[
\begin{bmatrix}
\theta & * & \cdots & \cdots & * \\
\theta & \theta & * & \cdots & * \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
\theta & \cdots & \cdots & \cdots & * \\
\theta & \cdots & \cdots & \cdots & \theta \\
\end{bmatrix}
\]

then $A \approx B = \begin{bmatrix} B_1 & B_3 \\ 0 & B_4 \end{bmatrix}$. 

The following theorem is also graph-theoretically based and holds for any weighted graph over a semiring.

**Theorem 2.20.** If G be a graph in which every vertex has out degree at least one, then G has a circuit.

**Proof.** If G has no circuit, then as noted in 2.18, we can relabel the vertices of G so that there is no edge from $S_i$ to $S_j$ if $i<j$. But then vertex $S_n$ must have out-degree zero, which is a contradiction. Therefore G must have a circuit. □

### 2.4 Polynomial Forms

The definitions in this section are the same as for rings. Let $(\mathbb{R}, +, \times)$ be a commutative semiring with identity. Let $R[x]$ be the collection of all finite ordered subsets $(a_0, a_1, \ldots, a_n)$ of $\mathbb{R}$ where

1. $n$ is an arbitrary nonnegative integer.
2. Either $a_n \neq 0$, or $n=0$ and $a_0=0$.

To make $R[x]$ into a semiring we define addition and multiplication.

**Definition 2.21 (Polynomial forms over $(\mathbb{R}, +, \times)$).**

1. $p = (p_0, p_1, p_2, \ldots, p_n)$, with $p_i \in \mathbb{R}$.
2. $\partial p = n$
3. The zero polynomial has no degree.

Let p and q be polynomial forms, then we define the operation of addition of these two polynomials.

**Definition 2.22 (Addition).** If $p=(p_0, p_1, \ldots, p_n)$ and $q=(q_1, q_2, \ldots, q_m)$ with $n>m$, then $p \boxplus q = (p_0 + q_0, p_1 + q_1, \ldots, p_n + q_m, p_{n+1}, \ldots, p_n)$.

**Proposition 2.23 (Properties of $\boxplus$).**

1. $R[x]$ is closed under $\boxplus$ since $R$ is closed.
2. $\boxplus$ is commutative since $\mathbb{R}$ is commutative.
3. $\boxplus$ is associative since $\mathbb{R}$ is associative.
4. $\theta = (\theta, \theta, \theta, \ldots, \theta)$ is the additive identity.
Definition 2.24 (Scalar Multiplication). If $\alpha \in R$ and $p=(p_0, p_1, \ldots, p_n)$, then $(\alpha \Box p) = (\alpha \times p_0, \alpha \times p_1, \ldots, \alpha \times p_n)$. We use, here, that $\alpha \Box \theta = \theta$.

Definition 2.25 (Multiplication). If $p=(p_0, p_1, \ldots, p_n)$, and $q=(q_0, q_1, \ldots, q_m)$, then $p \boxtimes q = (a_0, c_1, c_2, \ldots, c_r)$, where $c_j = \sum_{j+k=i} a_j b_k$.

This multiplication is just the normal Cauchy product of two polynomials.

Proposition 2.26 (Properties of Multiplication).

Let $\alpha, \beta \in R$, and $p, q, r$ are polynomial forms.

1. $\alpha \Box (p \boxtimes q) = \alpha \Box p \boxtimes \alpha \Box q$
2. $(\alpha + \beta) \Box p = \alpha \Box p \boxtimes \beta \Box p$
3. $e \Box p = p \boxtimes e = p$
4. $R[x]$ is closed under $\boxtimes$ since $R$ is closed.
5. $\boxtimes$ is commutative since $R$ is commutative and associative.
6. $\boxtimes$ is distributive over $\boxplus$.

With the properties above, we have

Theorem 2.27. The system $(R[x], \boxplus, \boxtimes)$ is a semiring.

The notation which is sometimes used for polynomial forms is $p=(p_0, p_1, \ldots, p_n) = p_0 + p_1 x + p_2 x^2 + \cdots + p_n x^n$, where ’$x$’ is a place holder.

There is no division algorithm for a general semiring.
3 Zerosumfree Semirings

A zerosumfree semiring is a semiring that obeys the additional axiom that if \(a + b = \theta\) then \(a = b = \theta\). This condition says that no element of the semiring \(R\) has an additive inverse. The Path Algebras and multiset algebra are examples of zerosumfree semirings.

**Definition 3.1.** If \(G\) is a graph, then \(E\) is called the **connectivity matrix** associated with \(G\).

\[
E = \begin{cases} 
e & \text{if an arc exists from } S_i \text{ to } S_j \\ \theta & \text{otherwise} \end{cases}
\]

Let \(R\) be a zerosumfree semiring. We note that since \(e \ne \theta\) in \(R\), then \(e + e \ne \theta\) and \(e \times e = e\). We will use the notation \(B > \theta\) to mean that every element of \(B \ne \theta\).

**Note 3.2.** We will assume that \(R\) contains no zero divisors. This is certainly true for the semirings presented in this thesis. In applications this is required for otherwise a path could exist in a graph with a path product equal to zero. This would defeat the use of path products as we require that if a path exists then its path product is not zero.

**Theorem 3.3.** \(G\) is strongly connected if and only if \(I + E + \cdots + E^{n-1} > \theta\).

**Proof.**

\((\Rightarrow)\) Suppose \(G\) is strongly connected and let \(E\) be its connectivity matrix. Let \(B = I + E + \cdots + E^{n-1}\). For all \(i, j\), there is a path from \(S_i\) to \(S_j\). Suppose that \(i \neq j\) and \((B)_{ij} = \theta\). Then \((E)_{ij} + (E^2)_{ij} + \cdots + (E^{n-1})_{ij} = \theta\). Since \(R\) is zerosumfree we have \((E^k)_{ij} = \theta\) for all \(k\). This implies that the sum of all path products must be zero. Again, zerosumfree implies that all path products must be zero. This is a contradiction since \(G\) is strongly connected and a t-step path exists from \(S_i\) to \(S_j\) and \((E^t)_{ij} = e \neq \theta\). Therefore \(B > \theta\).

\((\Leftarrow)\) Suppose that \(B > \theta\). Fix \(i\) and \(j\). Then \(B_{ij} \neq \theta\) shows that there exists a \(k\) such that \((E^k)_{ij} \neq \theta\). So at least one path product is not zero. Therefore there is a path from \(S_i\) to \(S_j\). Since this is true for every pair \((i, j)\), the result follows.

The theorem above, as well as the theorem below, can be generalized to the adjacency matrix of \(G\) provided that the semiring \(R\) has no zero divisors (which we will assume).

**Theorem 3.4.** \(G\) is strongly connected if and only if \((I + E)^{n-1} > \theta\).

**Proof.** \((I + E)^{n-1} = I + (n-1)^1 E + (n-1)^2 E^2 + \cdots + E^{n-1}\). Let \(B = I + (n-1)^1 E + (n-1)^2 E^2 + \cdots + E^{n-1}\). Here, we use multiplication as a shortened form of repeated addition, in other words, \((n-1)^1 E = E + E + \cdots + E\).

\((\Rightarrow)\) Suppose that \(G\) is strongly connected and \(E\) is the connectivity matrix of \(G\). Fix \(i, j\), with \(i \neq j\). Since \(G\) is strongly connected then there is a \(k\)-cycle from \(S_i\) to \(S_j\) with \(1 \leq k \leq n - 1\). \((E^k)_{ij} = e\), and \((n-1)^k E^k > \theta\). Therefore \((B)_{ij} \neq \theta\).
(\leq) Suppose \((I + E)^{n-1} > \theta\). So \((B)_{ij} \neq \theta\) for all \(i,j\). Since \(R\) is zerosumfree then \((B)_{ij} \neq \theta\) if and only if \((I + E + E^2 + \cdots + E^{n-1})_{ij} \neq \theta\). And by Theorem 3.3 we have that \(G\) is strongly connected.

\(\square\)

The following theorem is a generalization of the scaling that is done in \(\mathfrak{M}^+\), or in \(\mathbb{R}^+\).

**Lemma 3.5.** If \(A^n = \theta\), then

\[ A (\lambda^{n-1} I + \lambda^{n-2} + \cdots + A^{n-1}) + \lambda^n I = \lambda^n I + \lambda^{n-1} A + \lambda^{n-2} A^2 + \cdots + \lambda A^{n-1} \quad (7) \]

We make the following definition to aid the writing of the above lemma.

**Definition 3.6.** Let \(A^\dagger = \lambda^{n-1} I + \lambda^{n-2} + \cdots + A^{n-1}\)

With this definition Lemma 3.5 becomes

**Lemma 3.7.** \(A A^\dagger + \lambda^n I = \lambda A^\dagger\)

Theorem 3.8 illustrates how a nilpotent matrix and its associated graph relate to the eigenvalues of the matrix. This theorem is a nice generalization of the theorems in \(\mathfrak{M}^+\). We use that \(R\) is zerosumfree and has no zero divisors.

**Theorem 3.8.** Suppose \(A \neq \theta\), then the following are equivalent:

(a) \(G(A)\) has no cycles.
(b) \(A \simeq B \equiv \frac{\theta}{\text{per}} = \begin{bmatrix} \theta & * & \cdots & \cdots & * \\ \theta & \theta & * & \cdots & * \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ \theta & \cdots & \cdots & \ddots & * \\ \theta & \cdots & \cdots & \cdots & \theta \end{bmatrix} \)
(c) \(A\) is nilpotent. If so then \(\theta\) is the only eigenvalue.

(d) If, in addition, any irreducible matrix of size at least \(2 \times 2\) has a nonzero eigenvalue, then \(\theta\) is the only eigenvalue of \(A\)

Item (d) above is not true for matrices over a general semiring. It is true for \(\mathbb{R}^+\), and Max-Times, but not for msets.

**Proof.** We will prove \((a) \iff (b) \iff (c) \iff (d)\), and \((b) \implies (d)\)

(b) \(\implies (a)\) This is clear, as there in no path from \(S_i\) to \(S_j\) if \(i \leq j\).

(b) \(\implies (c)\) This, too, is seen from the fact that \(B^n = \theta\).

\[\Box\]
\[(c) \implies (b) \quad \text{Suppose } A \text{ is nilpotent. Without loss of generality, we may assume that}\]
\[
A \approx B = \begin{bmatrix}
A_1 & ? & ? & ? \\
0 & A_2 & ? & ? \\
0 & 0 & \ddots & ? \\
0 & 0 & \cdots & A_q
\end{bmatrix}
\]

which is the Frobenius Normal Form (FNF) of \( A \), where \( A_i = [\theta]_{1^x1} \), or \( A_i \) is irreducible.

So, \( A = PBP^{-1} \). So there exist \( k \) such that \( A^k = \theta = PBP^{-1} \approx \begin{bmatrix}
A_1^k & ? & ? & ? \\
0 & A_2^k & ? & ? \\
0 & 0 & \ddots & ? \\
0 & 0 & \cdots & A_q^k
\end{bmatrix} \]

Since \( A_1^k = \theta \) and \( A_i \) is irreducible. Consider the first block \( A_1 \). Suppose that \( A_1 \) contains a \( t \)-cycle through the first \( t \) nodes. Then \( (A_1^t)_{11} \neq \theta \). Therefore the index of nilpotency must be greater than \( t \). But \( (A_1^t)_{11} \neq \theta \) for all \( t \). Therefore there is no number such that \( A_1^n = \theta \).

Since \( A_1^k = \theta \) and \( A_i \) is irreducible, then \( A_i = \theta_{1^x1} \).
Therefore the FNF is strictly upper triangular.

\[(b) \implies (c) \quad A \approx B = \begin{bmatrix}
\theta & a_{12} & \cdots & \cdots & a_{1n} \\
\theta & \theta & a_{23} & \cdots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\theta & \theta & \cdots & \theta & a_{n-1,n} \\
\theta & \theta & \cdots & \cdots & \theta
\end{bmatrix} \quad (8)
\]

\( z = \begin{bmatrix} x_1, \theta, x_2, \ldots, \theta \end{bmatrix} \)

is an eigenvector for the eigenvalue \( \theta \).
Therefore \( \theta \) is an eigenvalue.

Now, suppose the \( \lambda \neq \theta \) is an eigenvalue of \( A \). So \( Ax = \lambda x \) with \( x \neq 0 \).

\[
\begin{bmatrix}
\theta & a_{12} & \cdots & \cdots & a_{1n} \\
\theta & \theta & a_{23} & \cdots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\theta & \theta & \cdots & \theta & a_{n-1,n} \\
\theta & \theta & \cdots & \cdots & \theta
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_{n-1} \\
x_n
\end{bmatrix} = \lambda
\begin{bmatrix}
x_1 \\
x_2 \\
\vdots \\
x_{n-1} \\
x_n
\end{bmatrix}
\]

The last equation of (9) yields \( \theta = \lambda x_n \implies x_n = \theta \), since \( \lambda \neq \theta \).

The next to last equation of (9) yields: \( a_{n-1,n}x_n = \theta = \lambda x_{n-1} \implies x_{n-1} = \theta \).

Continuing backwards to the first equation, we get:
\( a_{12}x_2 = a_{12}(\theta) = \theta = \lambda x_1 \implies x_1 = \theta \).

Therefore \( x = [\theta, \theta, \ldots, \theta]^T \), which is a contradiction to the fact that \( x \neq \theta \).
Therefore \( \theta \) is the only eigenvalue of \( A \).
((d) \implies (c)) \quad \text{We need to show that if } \theta \text{ is the only eigenvalue of } A \text{ then } A \text{ is nilpotent.} \\
Suppose that } A \text{ is not nilpotent. Then } A \text{ can be permuted to the form} \\
\begin{align*}
A \approx_{\text{per}} M &= \begin{bmatrix}
\theta & & & \\
& \ddots & & \\
& & \ddots & \\
0 & & & D
\end{bmatrix} = \begin{bmatrix}
M_1 & M_3 \\
0 & M_4
\end{bmatrix}, \text{ where } D \text{ is not } \theta_{1\times1}. \\
M_1 &= \begin{bmatrix}
\theta & & & \\
& \ddots & & \\
& & \ddots & \\
0 & & & D
\end{bmatrix} = \begin{bmatrix}
A & C \\
0 & D
\end{bmatrix}.
\end{align*}
Since } D \text{ is irreducible then, by assumption, } D \text{ has a nonzero eigenvalue, say } \lambda. \text{ Let } \underline{u} \neq \theta \text{ be an associated eigenvector for } D. \\
\text{Define } \underline{w} = \begin{bmatrix} A^t C \underline{u} \\ \lambda^n \underline{u} \end{bmatrix}. \text{ We know that } \underline{w} \neq \theta \text{ since } \lambda \neq \theta, \text{ and } \underline{u} \neq \theta. \\
\text{Consider } M_1 \underline{w}.
\begin{align*}
M_1 \underline{w} &= \begin{bmatrix}
A & C \\
0 & D
\end{bmatrix} \begin{bmatrix} A^t C \underline{u} \\ \lambda^n \underline{u} \end{bmatrix} = \begin{bmatrix} AA^t C \underline{u} + \lambda^n C \underline{u} \\ \lambda^n D \underline{u} \end{bmatrix} = \begin{bmatrix} (AA^t + \lambda^n I)C \underline{u} \\ \lambda^n D \underline{u} \end{bmatrix} \\
&= \begin{bmatrix} \lambda A^t C \underline{u} \\ \lambda^n \underline{u} \end{bmatrix} = \lambda \begin{bmatrix} A^t C \underline{u} \\ \lambda^n \underline{u} \end{bmatrix} = \lambda \underline{w}
\end{align*}
Therefore, } \underline{w} \text{ is an eigenvector for } M_1 \text{ and } \lambda \neq \theta \text{ is an eigenvalue for } M_1. \text{ So} \\
\begin{align*}
M \begin{bmatrix} \underline{u} \\ \theta \end{bmatrix} &= \lambda \begin{bmatrix} \underline{u} \\ \theta \end{bmatrix}
\end{align*}
and } \lambda \neq \theta \text{ is an eigenvalue of } M, \text{ which contradicts the fact that } M \text{ has only } \theta \text{ as an eigenvalue. Therefore } A \text{ must be nilpotent.} \quad \Box

We note that not all matrices in a particular semiring possess an eigenvalue.
4 Idempotent Semirings (Path Algebras)

Path Algebras have been developed to answer questions pertaining to weighted graphs. Examples include finding the shortest path or longest path in a graph. A Path Algebra is a specific subclass of idempotent semirings. Recall that an idempotent semiring satisfies axioms (1)-(4) along with axiom (6) on page 3. Some authors also refer to these structures as idempotent dioids. Included in this section are some examples of the different types of path algebras that are used to work with weighted graphs. Table 1 lists some of these different algebra systems. Two particular path algebras are presented in this thesis. We investigate the Max-Plus algebra and the Max-Times algebra. These systems are used to determine the longest path of a weighted graph.

Table 2: The family of \((\max,+)\) and tropical semirings

5 Max-Plus Algebra

The Max-Plus Algebra has been developed to answer questions pertaining to the longest path in a graph. The following example shows one application of this field.

5.1 Example

We begin with an example to introduce the subject. This will allow us to illustrate many of the different topics that will be covered in this thesis. This is an example of using the Max-Plus algebra system to linearize a problem which is nonlinear in the conventional algebra.

Example 5.1. Suppose we look at a simple train network. The train network is between three cities with intercity routes also. Suppose that there are two trains at each station; one for the intracity track and one for the intercity track. Figure 2 shows a diagram which represents the train network. To simplify the problem we will assume that the times given include the time needed to board the train, the time required for exiting, and the time required for change-overs.

Suppose we let \( x_i \) represent the time that a train leaves station \( i \), for \( i = 1,2,3 \). We let \( x_i(k) \) represent the \( k^{th} \) time a train leaves station \( i \). Let us suppose, first of all, that each of the trains leave at time \( = 0 \). Therefore we have \( x_1(1) = 0 \), \( x_2(1) = 0 \), and \( x_3(1) = 0 \). Then we can see that the time
at which the trains leave the station the second time is:

\[
\begin{align*}
x_1(2) &= \max\{x_1(1) + 3, x_3(1) + 6\} \\
x_2(2) &= \max\{x_2(1) + 2, x_1(1) + 5\} \\
x_3(2) &= \max\{x_3(1) + 4, x_2(1) + 7\}
\end{align*}
\]

Note the long delay due to waiting for change-overs. This set of equations is certainly nonlinear. The question, now, is: Can this set of equations be made into a linear system? The answer is “yes” if we change to a different algebra system. Define \(a \oplus b\) to be the \(\max(a, b)\) and \(a \odot b\) to be \(a + b\) in the conventional algebra. Then the set of equations above can be written as:

\[
\begin{align*}
x_1(2) &= 3 \odot x_1(1) \oplus 6 \odot x_3(1) \\
x_2(2) &= 2 \odot x_2(1) \oplus 5 \odot x_1(1) \\
x_3(2) &= 4 \odot x_3(1) \oplus 7 \odot x_2(1)
\end{align*}
\]

This looks very similar to a linear algebra problem. We will assume the usual laws of arithmetic (and matrix arithmetic) apply as usual in this example. If we let \(x(k) = [x_1(k), x_2(k), x_3(k)]^T\) then \(x(k)\) represents the \(k^{th}\) time that each train leaves the station. The above equations can be written in matrix form as \(x(2)^T = x(1)^T \odot x\), where \(A = \begin{bmatrix} 3 & 5 & -\infty \\ -\infty & 2 & 7 \\ 6 & -\infty & 4 \end{bmatrix}\). Here, \(a_{ij}\) is the travel time from station \(i\) to station \(j\). Note that \(-\infty\) is included in the matrix where no path (route) exists, since \(\theta \oplus a = a\), and \(\theta \odot a = -\infty\) for all \(a \in \mathbb{R}^+\).

**Note 5.2.** We may use multiplication by \(x\) on the right if we are willing to use \(A^T\) instead of \(A\).

This yields: \(x(2)^T = x(1)^T \odot A\), or \(x(2) = A^T \odot x(1)\).

From above we have \(x(2)^T = [6, 5, 7]\). For \(x(3)\), we have \(x(3) = A^T \odot x(2) = A^T \odot (A^T \odot x(1)) = (A^T)^2 \odot x(1)\), and in general:

\(x(k) = A^T \odot x(k-1) = (A^T)^{k-1} \odot x(1)\).
Starting with the initial value \( \mathbf{z} (1)=[0,0,0]^T \), we iterate to get:

\[
\begin{bmatrix}
\mathbf{z}^{(1)} \\
\mathbf{z}^{(2)} \\
\mathbf{z}^{(3)} \\
\mathbf{z}^{(4)} \\
\mathbf{z}^{(5)} \\
\mathbf{z}^{(6)} \\
\mathbf{z}^{(7)}
\end{bmatrix} =
\begin{bmatrix}
0 \\
0 \\
0 \\
6 \\
5 \\
7 \\
6
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 \\
0 \\
0 \\
13 \\
11 \\
7 \\
6
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 \\
0 \\
0 \\
18 \\
12 \\
7 \\
6
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 \\
0 \\
0 \\
24 \\
25 \\
7 \\
6
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 \\
0 \\
0 \\
31 \\
30 \\
7 \\
6
\end{bmatrix}
\rightarrow
\begin{bmatrix}
0 \\
0 \\
0 \\
36 \\
36 \\
7 \\
6
\end{bmatrix}
\]

This sequence of iterates has a period of 3.

If we start with \( \mathbf{z} (1)=[1,0,1]^T \), we get:

\[
\begin{bmatrix}
\mathbf{z}^{(1)} \\
\mathbf{z}^{(2)} \\
\mathbf{z}^{(3)} \\
\mathbf{z}^{(4)} \\
\mathbf{z}^{(5)} \\
\mathbf{z}^{(6)} \\
\mathbf{z}^{(7)}
\end{bmatrix} =
\begin{bmatrix}
1 \\
0 \\
1 \\
6 \\
6 \\
6 \\
6
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 \\
0 \\
1 \\
13 \\
13 \\
7 \\
7
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 \\
0 \\
1 \\
19 \\
19 \\
7 \\
7
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 \\
0 \\
1 \\
25 \\
25 \\
7 \\
7
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 \\
0 \\
1 \\
31 \\
31 \\
7 \\
7
\end{bmatrix}
\rightarrow
\begin{bmatrix}
1 \\
0 \\
1 \\
37 \\
37 \\
7 \\
7
\end{bmatrix}
\]

Notice from this sequence that the iterates have a period=1.

This leads to the question: For what starting values does the sequence of iterates lead to a period of 1?

As we look at this example in more depth we notice that there are four cycles in the graph. \( 1 \rightarrow 1 \), \( 2 \rightarrow 2 \), \( 3 \rightarrow 3 \), and \( 1 \rightarrow 2 \rightarrow 3 \rightarrow 1 \). The average length of these cycles are, respectively, \( \frac{1}{2} = 3 \), \( \frac{1}{2} = 2 \), \( \frac{1}{2} = 4 \), \( \frac{1}{2} = 6 \). The largest average cycle mean is 6. We also note from the iterates above that \( [1 \ 0 \ 1] \odot A = 6 \odot [1 \ 0 \ 1] \). Therefore, in the terms of linear algebra, \( [1 \ 0 \ 1]^T \) is a left eigenvector of \( A \) corresponding to the eigenvalue \( \lambda = 6 \).

In the conventional linear algebra, this would lead to the eigenvalue/eigenvector equation \( \mathbf{A} \mathbf{z} = \lambda \mathbf{z} \), or \( \mathbf{A}^T \mathbf{z} = \lambda \mathbf{z} \). We see from the above problem that \( \mathbf{z} = [1 \ 0 \ 1]^T \) and \( \lambda = 6 \) satisfies this equation.

### 5.2 Definitions

We begin with definitions and basic properties of this system. We then present some of the basic theorems of this algebra system. Many good references exist, including [13], [2], and [4].

**Definition 5.3.** The Max-Plus algebra is defined as:

(i) \( \mathbb{M} = \mathbb{R} \cup \{-\infty\} \), where \( \mathbb{R} \) represents the Real Numbers.

(ii) \( a \oplus b \equiv \max(a,b) \)

(iii) \( a \otimes b \equiv a + b \)

**Note 5.4.** We use the notation \( \mathbb{M}^+ \) to represent the algebraic system \( (\mathbb{M}, \oplus, \otimes) \). Many authors refer to this as the \((\max,+)\)-algebra.

In defining the \((\max,+)\) algebra we have the following:
(a) \( \theta = -\infty \) is the additive identity of \( \mathbb{M}^+ \), i.e. \( -\infty \oplus a = a \) for all \( a \in \mathbb{M}^+ \).

(b) \( e = 0 \) is the multiplicative identity of \( \mathbb{M}^+ \), i.e. \( -\infty \otimes a = a \) for all \( a \in \mathbb{M}^+ \).

Table 3 contains some examples of the basic mathematical operations in \( \mathbb{M}^+ \).

Table 3: Examples in \( (\max,+)) \) algebra

In what follows we will use \( \oplus \) and \( \otimes \) for the Max-Plus Algebra, and, \( + \) and \( \cdot \) for the conventional algebra.

**Proposition 5.5.** \( \mathbb{M}^+ \) is a zero-sumfree idempotent semiring.

In particular, we add that \( \mathbb{M}^+ \) is a semifield since all nonzero elements have a multiplicative inverse.

**Elementary Properties**

We begin by listing some of the elementary properties of the Max-Plus Algebra system.

**Proposition 5.6.**

(a) \( \mathbb{M}^+ \) is idempotent, i.e. \( a \oplus a = a \) for all \( a \in \mathbb{M}^+ \)

(b) \( a^k \equiv k \cdot a \quad \forall \ a \in \mathbb{M}^+ \), and \( \forall \ k \in \mathbb{N} \)

(c) \( k > 0 \implies \theta^k = \theta \).

(d) \( \theta^0 \) is undefined.

(e) \( \lambda \oplus \theta = \theta \), for all \( \lambda \)

(f) \( \theta \oplus \theta = \theta \)

(g) \( \theta \otimes \theta = \theta \)
(h) $\frac{\theta}{\tau}$ is undefined

(i) If $\lambda > \theta$, then $\lambda^{-1}\theta = \frac{\theta}{\lambda} = \theta$

(j) $\alpha^{(1/\lambda)} \equiv \frac{1}{\lambda} \cdot \alpha = \frac{\alpha}{\lambda}$ if $\lambda \neq \theta$

(k) $a \leq b \iff a \oplus b = b$

(l) $\theta \leq a$ for all $a \in \mathbb{M}^+$

(m) The normal hierarchy from the conventional algebra is used, namely:

(i) Exponents
(ii) Multiplication
(iii) Addition

Matrices

The usual properties of matrices from the previous sections on semirings and zero-sumfree semirings also hold for matrices in $\mathbb{M}^+$. Definition 5.7 allows for a translation of the matrix $A$.

**Definition 5.7.** If $A \in \mathbb{M}^{n \times n}_+, \lambda \in \mathbb{M}^+$, then $\lambda^{-1}A \equiv A - \lambda J$, where $J$ is the $n \times n$ matrix of all ones.

We include an example to show the matrix operations in $\mathbb{M}^+$.

**Example 5.8.**

\[
\begin{pmatrix} 2 & 3 \\ -\infty & 4 \end{pmatrix} \otimes \begin{pmatrix} -3 \\ 0 \end{pmatrix} = \begin{pmatrix} 3 \\ 4 \end{pmatrix}
\]

The work of this example in the conventional algebra is shown:

\[
\begin{pmatrix} 2 & 3 \\ -\infty & 4 \end{pmatrix} \otimes \begin{pmatrix} -3 \\ 0 \end{pmatrix} \equiv \begin{pmatrix} \max(2 + (-3), 3 + 0) \\ \max(-\infty + (-3), 4 + 0) \end{pmatrix} = \begin{pmatrix} 3 \\ 4 \end{pmatrix}
\]

Graphs

From Section 2 we have our basic definitions of graphs. We continue with our investigation of graphs in the $\mathbb{M}^+$ algebra.

**Definition 5.9.** A circuit mean is the average weight of a circuit which is expressed as $w(\tau)\frac{1}{\ell(\tau)}$ in the $(\max,+)\text{ algebra.}$ This is equivalent to calculating the arithmetic mean of the circuit; $\frac{w(\tau)}{\ell(\tau)}$ in the conventional algebra.

Given a circuit $\tau$, we will denote the average weight of a circuit $\tau$ by $\bar{\omega}(\tau)$. We will denote the set of circuits of $G(A)$ by $C(A)$.  

20
Note 5.10. If $G(B)$ contains at least one circuit then $C(B) \neq \emptyset$.

Definition 5.11. We define the maximal circuit mean of $A$, denoted by $\mu(A)$ as:

$$
\mu(A) = \begin{cases} 
\max_{\tau \in C(A)} \omega(\tau) & \text{if } C(A) \neq \emptyset \\
-\infty & \text{if } C(A) = \emptyset 
\end{cases}
$$

(13)

A circuit is called a critical circuit if $\omega(\tau) = \mu(A)$. We will use $CN(A)$ to denote the set of all nodes of all of the critical circuits of $A$.

A directed graph is strongly connected if there exists a path from any node in the graph to any other node in the graph. We say that $A$ is irreducible if and only if $G(A)$ is strongly connected. If $A$ is not irreducible then we say that it is reducible. Therefore, $A$ is reducible if and only if $G(A)$ is not strongly connected.

We include the following lemma which will be useful in our development of cycles.

Lemma 5.12. Suppose that $a,b,c,d$ are real numbers, with $b,d \geq 0$, then

$$
\max \left\{ \frac{a}{b}, \frac{a+c}{d} \right\} = \max \left\{ \frac{a}{b}, \frac{a+c}{d} \right\}
$$

(14)

Proof. Suppose, without loss of generality, $\frac{a}{b} \geq \frac{a+c}{d}$. Then

$$
\frac{a}{b} \geq \frac{c}{d}
$$

$$
ad \geq bc
$$

$$
ab + ad \geq ab + bc
$$

$$
a(b + d) \geq b(a + c)
$$

$$
\frac{a}{b} \geq \frac{a+c}{b+d}
$$

The result follows. $\square$

With the use of the lemma above, we have

Lemma 5.13. We only need to consider the cycles of the graph in the calculation of the maximum circuit mean.

Proof. Suppose we have a circuit $\tau$ which is made up of two separate circuits, say $\gamma$ and $\sigma$. We write $\tau = \gamma + \sigma$.

$$
\omega(\tau) = \frac{\sum_{i,j \in \gamma} a_{i,j} + \sum_{p,q \in \sigma} a_{p,q}}{\ell(\gamma) + \ell(\sigma)}
$$

$$
\omega(\gamma) = \frac{\sum_{i,j \in \gamma} a_{i,j}}{\ell(\gamma)}
$$

21
\[
\omega(\sigma) = \frac{\sum_{p,q \in \sigma} a_{p,q}}{\ell(\sigma)}
\]

By Lemma 5.12, above, we have that

\[
\max\{\omega(\gamma), \omega(\sigma), \omega(\tau)\} = \max\{\omega(\gamma), \omega(\sigma)\}
\]

\[\square\]

5.3 Eigenvalue / Eigenvector Analysis in Max-Plus algebra

We say that \( \lambda \in \mathbb{R}^+ \) is an eigenvalue of \( A \in \mathbb{R}_{n \times n}^+ \) if there exists a vector \( \vec{z} \neq \theta \) such that \( A \otimes \vec{z} = \lambda \otimes \vec{z} \). In this case we say that \( \vec{z} \) is an eigenvector of \( A \) corresponding to the eigenvalue \( \lambda \).

**Definition 5.14 (Eigenvalue-Eigenvector equations in the Max-Plus Algebra system).**

\[
A \otimes \vec{z} = \lambda \otimes \vec{z} \implies \left[ \begin{array}{cccc}
    a_{11} & a_{12} & \cdots & a_{1n} \\
    a_{21} & a_{22} & \cdots & a_{2n} \\
    \vdots & \vdots & \ddots & \vdots \\
    a_{n1} & a_{n2} & \cdots & a_{nn}
\end{array} \right] \otimes \left[ \begin{array}{c}
    x_1 \\
    x_2 \\
    \vdots \\
    x_n
\end{array} \right] = \lambda \otimes \left[ \begin{array}{c}
    x_1 \\
    x_2 \\
    \vdots \\
    x_n
\end{array} \right]
\]

\[15\]

\[
\implies \begin{cases}
\max\{a_{11} + x_1, a_{12} + x_2, \cdots, a_{1n} + x_n\} = \lambda + x_1 \\
\max\{a_{21} + x_1, a_{22} + x_2, \cdots, a_{2n} + x_n\} = \lambda + x_2 \\
\vdots \quad \vdots \\
\max\{a_{n1} + x_1, a_{n2} + x_2, \cdots, a_{nn} + x_n\} = \lambda + x_n
\end{cases}
\]

\[16\]

We begin with a few definitions and some properties of matrices in the Max-Plus algebra system. We use \( J \) for the matrix of all ones, i.e. \( J = \vec{e} \vec{e}^T \), where \( \vec{e} \) is the vector of all ones.

**Definition 5.15.** Suppose \( A \in \mathbb{R}_{n \times n}^+ \) and \( \lambda \in \mathbb{R}^+ \), then

(a) \( (\lambda \otimes A)_{ij} \equiv \lambda + a_{ij} \)

(b) \( \lambda^{-1} \otimes A = \frac{A}{\lambda} \equiv A - \lambda J \), if \( \lambda \neq \theta \).

**Lemma 5.16.** Suppose \( A, B \in \mathbb{R}_{n \times n}^+ \), \( \lambda \in \mathbb{R}^+ \), then

(a) \( \lambda \otimes (\frac{A}{\lambda}) = \lambda \otimes (\lambda^{-1} \otimes A) = A \)

(b) If \( \lambda > \theta \) and \( A \) is nilpotent then \( \frac{A}{\lambda} \) is nilpotent.

(c) \( \frac{A^B}{\lambda} = \frac{A^B}{\lambda} \)
(d) If \( \lambda > \theta \) and \( A^n = \theta \), then \( \left( \frac{A}{\lambda} \right)^n = \theta \)

Proof.

(a) \[ \lambda + (a_{i,j} - \lambda) = [a_{ij}] \]

(b)

\[
A = \begin{bmatrix}
\theta & \cdot & \cdot \\
\cdot & \theta & \cdot \\
\cdot & \cdot & \theta
\end{bmatrix} \rightarrow \begin{bmatrix}
\theta / \lambda & \cdot & \cdot \\
\cdot & \theta / \lambda & \cdot \\
\cdot & \cdot & \theta
\end{bmatrix} = \begin{bmatrix}
\theta & \cdot & \cdot \\
\cdot & \theta & \cdot \\
\cdot & \cdot & \theta
\end{bmatrix}
\]

(c)

\[
\bigoplus_k \left( \frac{A}{\lambda} \right)_{ik} \otimes \left( \frac{B}{\lambda} \right)_{kj} \equiv \max_k \{ (a_{ik} - \lambda) + (b_{kj} - \lambda) \} = \max_k \{ (a_{ik} + b_{kj}) \} - 2\lambda = \frac{AB}{\lambda^2} \quad (18)
\]

(d) If \( \lambda \neq \theta \), then

\[
\left( \frac{A}{\lambda} \right)^n = A^n = \frac{\theta}{\lambda^n} \equiv (-\infty - n \cdot \lambda) = -\infty = \theta
\]

Definite Matrices

In this section we give a brief overview of the subject of definite matrices. See [13] for a thorough introduction to the theory of definite matrices in the Max-Plus algebra. The theory of definite matrices is important as a first step in the development of eigenvalue-eigenvector equations. These matrices are used to simplify the equations, for, as we will see, the eigenvectors are easily found for a matrix in the Max-Plus algebra.

**Definition 5.17.** A matrix, \( B \), is said to be **definite** if \( C(B) \neq \emptyset \), \( w(\gamma) \leq e \), for all circuits \( \gamma \in G(B) \), and suppose that there exists at least one circuit, \( \tau \), with \( w(\tau) = e \).

We include some of the basic theorems on definite matrices from [13]. We present no proofs for these theorems but refer to [13] for details. These theorems are included for completeness.

**Definition 5.18.** Suppose \( B \) is definite. Let

1. \( B^+ = B \oplus B^2 \oplus \cdots \oplus B^n \)
2. \( B^\dagger = I \oplus B \oplus \cdots \oplus B^{n-1} \)

**Theorem 5.19.** Suppose \( B \) is definite. Then:
(1) $BB^\dagger = B^+$

(2) $B^r \leq B^+$ $\forall r \geq 1$

(3) $I \oplus B \oplus B^2 \oplus \cdots \oplus B^{n-1} = I \oplus B \oplus B^2 \oplus \cdots \oplus B^n$

(4) $I \oplus B^+ = B^\dagger$

(5) $I \oplus B^+ = I \oplus B^+ \oplus B^k$, $\forall k > n$

(6) $BB^\dagger \oplus I = B^\dagger$

(7) $(I \oplus B)^{n-1} = B^\dagger$

(8) $B^+ = B(I \oplus B)^{n-1}$

(9) $B(I \oplus B^+) \oplus I = I \oplus B^+$

(10) $B^\dagger = \bigoplus_{k=0}^r B^k$, for all $r \geq n - 1$

(11) $B^r$ is definite $\forall r \geq 0$

(12) $B^+$ is definite

(13) $B^\dagger$ is definite

(14) There exist i such that $1 \leq i \leq n$ and $B^+_{ii} = e$

(15) $(B^+)^r \leq B^+$, for all $r \geq 1$

(16) $B^+ = B(I \oplus B)^r$ for all $r \geq (n - 1)$

(17) $BB^\dagger e_i = B^+ e_i$ for all $i \in CN(B)$

(18) $B(B^+ e_i) = e \otimes B^+ e_i$

(19) $e$ is an eigenvalue of $B$

(20) $B^+ e_i$ is an eigenvector of $B$, for all $i \in CN(B)$.

**Theorem 5.20.** Suppose $B$ is definite and suppose that node $j$ is an eigennode, a node on a critical circuit. Then

(1) $B^+$ is definite.

(2) $(B^+)^{\bar{j}j} = e$

**Theorem 5.21.** Suppose $B$ is definite and $(B^+)_{\bar{j}j} = e$ for some $j$. Then node $j$ is an eigennode of $G(B)$. 

24
**Theorem 5.22.** Suppose $B$ is definite, and $j$ is an eigennode of $G(B)$. Then $B \otimes \xi(j) = \xi(j)$, where $\xi(j)$ is the $j^{th}$ column of $B^+$.

*Proof.* We need to show that $B \otimes B^+ e_i = e \otimes B^+ e_i$. This is the result of Theorem 5.19, equation (18).

**Theorem 5.23.** Suppose $B$ is definite. If $\xi(h)$, $\xi(j)$ are fundamental eigenvectors of $B$ corresponding to equivalent eigen-nodes $h$ and $k$, respectively, then $\xi(h)$, and $\xi(j)$ are finite multiples of one another.

**Theorem 5.24.** Let $M_\omega = \omega^{-1} \otimes M \equiv M - \omega J$, where $\omega = \mu(M)$. Then $\mu(M_\omega) = 0$.

*Proof.* \[ \omega = \frac{\sum_{\gamma} M_{ij}}{\ell(\gamma)}, \quad \text{and} \quad \sum_{\gamma} M_{ij} = \omega \ell(\gamma) \]

\[ \mu(M_\omega) = \frac{\sum_{\gamma} (M_{ij} - \omega)}{\ell(\gamma)} = \frac{\sum_{\gamma} M_{ij}}{\ell(\gamma)} - \frac{\sum_{\gamma} \omega}{\ell(\gamma)} \]

\[ = \frac{\ell(\gamma) \cdot \omega}{\ell(\gamma)} - \frac{\ell(\gamma) \cdot \omega}{\ell(\gamma)} = \omega - \omega = 0. \]  

**Theorem 5.25.** Given $A$. If $w(\gamma) < e$ for all $\gamma \in G(A)$, then $A^t$ exists, and the equation $AX + I = X$ has $A^t$ as a solution.

Theorem 5.25 shows that $A^t$ plays the role of $(I - A)^{-1}$ in this context.

**Definition 5.26.** We say that $B$ is $e$-astic definite if $B$ is definite, and $(B)_{ij} \leq e$, for $(i,j = 1,2, \ldots, n)$.

**Theorem 5.27.** $B$ is $e$-astic definite if and only if $B$ is definite and the elements of $B$ form a $e$-astic set. In particular, if $B$ is row- $e$-astic or column-$e$-astic, then $B$ is $e$-astic definite.

**Theorem 5.28.** Suppose $B$ is $e$-astic definite. Then:

(i) $B^+$ is $e$-astic definite, and $B^r$ is $e$-astic definite for each $r \geq 1$.

(ii) If $\xi(h)$, and $\xi(k)$ are equivalent fundamental eigenvectors of $B$, corresponding to equivalent eigen-nodes $h$, $k$ respectively, then $\xi(h) = \xi(k)$.

(iii) Each fundamental eigenvector of $B$ is column-$e$-astic.

(iv) The fundamental eigenvector $\xi(j)$ corresponding to a given eigen-node $j$ of $G(B)$ contains components equal to $e$ in all positions corresponding to eigen-nodes equivalent to $j$.

**Theorem 5.29.** Suppose $B$ is $e$-astic definite. If $\xi(j)$, $\xi(k)$ are fundamental eigenvectors corresponding to eigen-nodes $j$, and $k$ of $G(B)$, and $j$, $k$ are not equivalent, then: either $(\xi(j))_k < e$ or $(\xi(k))_j < e$.  

25
**Theorem 5.30.** Suppose $B$ is $e$-astic definite. If $\xi(j_1), \xi(j_2), \ldots, \xi(j_s)$ are fundamental eigenvectors corresponding to pairwise non-equivalent eigen-nodes $j_1, j_2, \ldots, j_s$ respectively, then no one of $\xi(j_1), \xi(j_2), \ldots, \xi(j_s)$ is linearly dependent on the others.

**Theorem 5.31.** Suppose $B$ is row-$e$-astic. Let $\xi(j_1), \xi(j_2), \ldots, \xi(j_s)$ be a maximal set of non-equivalent fundamental eigenvectors for $B$ and let $\Phi(B)$ be the matrix whose columns are $\xi(j_1), \xi(j_2), \ldots, \xi(j_s)$, in that order. Then $\Phi(B)$ is doubly $e$-astic.

**Theorem 5.32.** Suppose $B$ is definite. Then each element of the eigenspace of $B$ is an eigenvector of $B$ with corresponding eigenvalue equal to $e$.

**Theorem 5.33.** Suppose $B$ is $e$-astic definite. Let $\eta$ be an eigenvector of $B$ having corresponding eigenvalue $e$. If $h$ and $k$ are (distinct) equivalent eigen-nodes in $G(B)$, then $(\eta)_h = (\eta)_k$.

**Theorem 5.34.** Suppose $B$ is $e$-astic definite. Let $\eta$ be a finite eigenvector of $B$ having corresponding eigenvalue $e$. If $j$ is a non-eigen-node in $G(B)$ then there is an eigen-node $d$ of $G(B)$ such that $(\eta)_j = (B^+)_jd \otimes (\eta)_d$.

**Theorem 5.35.** Suppose $B$ is $e$-astic definite. If $\eta$ is a finite eigenvector having corresponding eigenvalue $e$, then $\eta$ lies in the eigenspace of $B$.

**General Matrices**

In this section we investigate the theory for general matrices in $\mathcal{M}^+$. The following theorem is analogous to the theorem from Nonnegative matrices.

**Theorem 5.36.** $\theta = -\infty$ is an eigenvalue of $A$ if and only if $A$ has an infinite column.

*Proof.* From [4],

If $(-\infty, x)$ is an eigenpair of $A$ and if $x_j$ is finite, then it follows from the eigenvalue-eigenvector equation that the $j$-th column of $A$ is $-\infty$. Conversely, if the $j$-th column of $A$ is $-\infty$, then a vector with all components $-\infty$ except the $j$-th component serves as an eigenvector of $A$ with $-\infty$ as the eigenvalue. \(\Box\)

**Corollary 5.37.** If $A$ is irreducible, then any eigenvalue is finite, i.e. if $\lambda \in \sigma(A)$, then $\lambda > -\infty$.

*Proof.* This is a corollary of Theorem 3.8. If $A$ is irreducible, then $A$ cannot have an infinite column. Therefore $-\infty$ is not an eigenvalue of $A$. So any eigenvalue must be finite. \(\Box\)

**Theorem 5.38 ($\mathcal{M}^+$).** If $A$ has a partly infinite eigenvector, then $A$ is reducible.

*Proof.* The proof given here is essentially the proof given in [4]. Let $(\lambda, x)$ be an eigenpair of $A$ with $x$ partly infinite. If $\lambda = -\infty$, then by Theorem 5.36, we conclude that $A$ has an infinite column and hence $A$ is reducible.
So suppose $\lambda$ is finite. We assume, without loss of generality, that $x=[y,-\infty]^T$, where $y$ is finite. Partition $A$ conformally, so that we have

$$
\begin{bmatrix}
A_{11} & A_{12} \\
A_{21} & A_{22}
\end{bmatrix} \otimes \begin{bmatrix}
y \\
-\infty
\end{bmatrix} = \lambda \otimes \begin{bmatrix}
y \\
-\infty
\end{bmatrix}
$$

Then $A_{21} \otimes y = \lambda \otimes -\infty$. Since $y$ is finite, then $A_{21} = -\infty$, and hence $A$ is reducible. \hfill \square

The following is a corollary of Theorem 5.38.

**Corollary 5.39.** If $A$ is irreducible, then any eigenvector of $A$ is finite.

The next theorem has a analogous theorem from the nonnegative matrices.

**Theorem 5.40.** For any matrix $A$, if $A \otimes x = \lambda \otimes x$, where $x > -\infty$ (x is finite), then $\lambda = \mu(A)$.

**Proof.** From [4].

If $\lambda = -\infty$, then as noted in Theorem 5.36, every column of $A$ must be $-\infty$ and hence $\lambda = \mu(A)$. So assume that $\lambda$ is finite. We have

$$
\max_j (a_{ij} + x_j) = \lambda + x_i, \quad \text{for } i=1,2,...,n
$$

and hence, in particular,

$$
a_{ij} + x_j - x_i \leq \lambda, \quad \text{for } i,j=1,2,...,n.
$$

Since $\lambda$ is finite, we must have $C(A) \neq \emptyset$ by Theorem 3.8. Let $\tau \in C(A)$ be the circuit formed by the edges $(i_1,i_2),(i_2,i_3),..., (i_k,i_1)$ and add the resulting inequalities to get $M_A(\tau) \leq \lambda$.

Now construct a directed graph $K$ with vertices $1,2,...,n$ and an edge $(i,j)$ if and only if there is equality in (24), i.e. $a_{ij} + x_j - x_i = \lambda$. By (23), each vertex in $K$ has out-degree at least one and hence, by Theorem 2.20, $K$ has a circuit, say $\tau$. Since $\lambda$ is finite, $K$ is clearly a subgraph of $G(A)$. Thus $\tau \in C(A)$, and furthermore, $M_A(\tau)=\lambda$. Therefore, $\lambda = \mu(A)$. \hfill \square

Work for Theorem 5.40 from (24)
\begin{align*}
a_{12} + x_2 & \leq \lambda + x_1 \\
a_{23} + x_3 & \leq \lambda + x_2 \\
\vdots & \vdots \\
a_{k1} + x_1 & \leq \lambda + x_k
\end{align*}

\begin{align*}
(a_{12} + \cdots + a_{k1}) + (x_1 + \cdots + x_n) & \leq \lambda^k + (x_1 + \cdots + x_n) \\
(a_{12} + \cdots a_{k1}) & \leq \lambda^k \\
M_A(\tau) & \leq \lambda
\end{align*}
or as

\begin{align*}
a_{12} \otimes x_2 & \leq \lambda \otimes x_1 \\
a_{23} \otimes x_3 & \leq \lambda \otimes x_2 \\
\vdots & \vdots \\
a_{k1} \otimes x_1 & \leq \lambda \otimes x_k
\end{align*}

\begin{align*}
\bigotimes_{ij} a_{ij} \otimes \bigotimes_{i} x_i & \leq \lambda^{\otimes k} \otimes \bigotimes_{i} x_i \\
\bigotimes_{ij} a_{ij} & \leq \lambda^{\otimes k} \\
M_A(\tau) & \leq \lambda
\end{align*}

The following theorem is one of the main theorems in the theory of matrices over \(\mathbb{M}^+\).

**Theorem 5.41.** If \(A \in \mathbb{M}_{n \times n}^+\), then \(\mu(A)\) is an eigenvalue of \(A\).

**Proof.** The proof given here is essentially that given in [3]. If \(C(A) = \emptyset\), then \(\mu(A) = -\infty\) and it is an eigenvalue of \(A\) by Theorem 3.8. So assume that \(C(A) \neq \emptyset\), in which case \(\mu(A)\) must be finite. Let \(B\) be the matrix with \(b_{ij} = a_{ij} - \mu(A)\) (i.e. \(B = (\mu(A))^{-1} \otimes A\)) for all \(i,j\), and let \(B^+ = B \oplus B^2 \oplus \cdots \oplus B^n\). Let \(j \in \{1,2,\ldots,n\}\) be a vertex which belongs to a critical circuit in \(C(B)\). Any path from \(j\) to itself in \(G(B)\) must have weight at most zero and since \(j\) belongs to a critical circuit, there is at least one path from \(j\) to itself of weight zero. Thus \(B_{jj}^+ = 0\) and, in particular, \(B_j^+\), the \(j\)-th column of \(B^+\), is not \(-\infty\).

Now observe that for any \(i\), the maximal weight of a path, of any length, from \(i\) to \(j\) may also be expressed as

\[28\]
$$\bigoplus_{k=1}^{n} b_{ik} \otimes B^+_{kj}$$  \hspace{1cm} (25)$$

since there exists such a path (in which a vertex may occur more than once) of length at least two, in view of the fact that j is on a critical circuit. However, (25) is precisely the $i^{th}$ entry of $B \otimes B^+_j$. Therefore, $B \otimes B^+_j = B^+_j = 0 \otimes B^+_j$, and hence $(0,B^+_j)$ is an eigen-pair of $B$. Now

$$A \otimes B^+_j = \mu(A) \otimes B \otimes B^+_j = \mu(A) \otimes B^+_j$$  \hspace{1cm} (26)$$

and therefore $\mu(A)$ is an eigenvalue of $A$. $

\textbf{Theorem 5.42.}$ If $A$ is irreducible, then $\mu(A)$ is only eigenvalue of $A$ and every eigenvector corresponding to $\mu(A)$ is finite.

\textit{Proof.} The proof given here is from [4] and is included for completeness. Since $A$ is irreducible, using an argument as in Theorem 3.8, we see that $C(A) \neq \emptyset$ and hence $\mu(A)$ is finite. Let $B$ be the $n \times n$ matrix with $b_{ij} = a_{ij} - \mu(A)$ for all i,j.

I.e. $A = \mu(A) \otimes B$, or $B = (\mu(A))^{-1} \otimes A$.

Define $B^+$ by

$$B^+ = B \oplus B^2 \oplus \cdots B^n$$  \hspace{1cm} (27)$$

Then:

$$B^+ \geq B^k, \forall k \geq n + 1$$  \hspace{1cm} (28)$$

Let $\tau \in C(A)$ be such that $M_A(\tau) = \mu(A)$ and let j be any vertex that belongs to $\tau$. Any path from j to itself in $G(B)$ must have weight at most zero, and because j is in $\tau$, there is at least one path from j to itself in $G(B)$ with weight zero. Thus $B^+_j = 0$ and, in particular, $B^+_j$, the j-th column of $B^+$, is not $-\infty$.

For any i, the maximal weight of a path in $G(B)$ (of any length) from i to j may also be expressed as

$$\bigoplus_{k} b_{ik} \otimes B^+_{kj}$$  \hspace{1cm} (29)$$

since there exists such a path (in which a vertex may occur more than once) of length at least two, in view of the fact that j is in $\tau$. However (29) is precisely the $i^{th}$ entry of $B \otimes B^+_j$. Therefore $B \otimes B^+_j = B^+_j = 0 \otimes B^+_j$, and hence $(0,B^+_j)$ is an eigenpair of $B$. Now

$$A \otimes B^+_j = \mu(A) \otimes B \otimes B^+_j = \mu(A) \otimes B^+_j$$  \hspace{1cm} (30)$$

and hence $\mu(A)$ is an eigenvalue of $A$. $

29
The following is a well-known theorem from linear algebra.

**Theorem 5.43.** If $A$ is a nonnegative matrix then $A$ and $A^T$ have the same eigenvalues.

In $\mathcal{M}^+$ things differ from their nonnegative counterparts.

**Note 5.44.** If $A \in \mathcal{M}_{n \times n}^+$, then $A$ and $A^T$ may have different eigenvalues.

The following example illustrates this fact for a small matrix over $\mathcal{M}^+$.

**Example 5.45.** If $A = \begin{bmatrix} 5 & -\infty \\ 2 & 6 \end{bmatrix}$, then

$$
A \otimes \begin{bmatrix} -\infty \\ 0 \end{bmatrix} = 6 \otimes \begin{bmatrix} -\infty \\ 0 \end{bmatrix}
$$

and it can be shown that 6 is the only eigenvalue for $A$.

For $A^T$, we see that

$$
\begin{bmatrix} 5 & 2 \\ -\infty & 6 \end{bmatrix} \otimes \begin{bmatrix} 0 \\ -\infty \end{bmatrix} = 5 \otimes \begin{bmatrix} 0 \\ -\infty \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 5 & 2 \\ -\infty & 6 \end{bmatrix} \otimes \begin{bmatrix} 0 \\ 4 \end{bmatrix} = 6 \otimes \begin{bmatrix} 0 \\ 4 \end{bmatrix}
$$

and, thus, 5 and 6 are eigenvalues. \[ \square \]

**Note 5.46.** Although a matrix, $A$, may have different eigenvalues than its transpose, $A^T$, we can say that $\mu(A) = \mu(A^T)$. This may be seen graphically since $A$ and $A^T$ are related by changing the direction of all paths in the graph. Therefore the same cycles are still critical cycles, since only the direction is changed. The maximum cycle mean of both graphs is the same.

The following three theorems come from Chen, et. al., [10]. These theorems provide a nice classification for the eigenvalues and eigenvectors of a matrix in the Max-Plus Algebra system.

**Theorem 5.47 (Canonical Form).** For the matrix $\overline{M}$ in Theorem 2.14, we can recombine its blocks by a permutation matrix $P_1$ to make it in the following form:

$$
\vec{M} = P_1 \overline{M} P_1^{-1} = \begin{bmatrix} A_1 & A_{12} & \cdots & A_{1k_0} & A_{10} \\ A_2 & \cdots & A_{2k_0} & A_{20} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & A_{k_0} & \cdots & A_{k_00} \\ A_0 \end{bmatrix}
$$

(32)

where $A_j$ ($j=1,2,\ldots,k_0,0$; $k_0 \leq k$) is also a block triangular submatrix; $G(A_j)$ ($j=1,2,\ldots,k_0,0$) consists of several strongly connected components; and $\vec{M}$ satisfies:
(1) $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_{k_0} \neq -\infty$ ($\lambda_j$ is the maximal circuit average weight of $M_j$) (j=1,2,...,k_0).

There is no circuit in $A_0$.

(2) The block of maximal circuit average weight $\lambda_j$ is at the right lower corner of $A_j$ and the maximal circuit average weights of other blocks in $A_j$ are all smaller than $\lambda_j$ (j=1,2,...,k_0).

(3) The condensation graph of $G(A_j)$ (j=1,2,...,k_0) is singly connected.

Proof. The basic proof is given in [10]. This proof is a modification of the proof given there, including expanding many of the steps given in that paper.

Consider $M = P M P^{-1} = \begin{bmatrix} M_1 & M_{12} & \cdots & M_{1k} \\ M_{21} & M_2 & \cdots & M_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & M_k \end{bmatrix}$ from Theorem 2.14.

Find the block $M_{k1}$ whose maximal circuit average weight is $\lambda_1$ in $M$. When a block above $M_{k1}$ has no path to $M_{k1}$, we shift it to the place next to $M_{k1}$. Continue this process until every block above $M_{k1}$ has a path to $M_{k1}$. Denote by $A_1$ the submatrix composed of $M_{k1}$ and the blocks above $M_{k1}$ in the transformed matrix. We can then continue the same process with the submatrix obtained by deleting the rows and columns of $M_{k1}$ and all rows and columns above this.

To illustrate how this is done, consider

$$
\overline{M} = \begin{bmatrix} V_1 & \cdots & V_k & \cdots & V_q \\ M_1 & \cdots & M_{k1} & \cdots & M_{1q} \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ M_{k1} & \cdots & M_{kq} & \vdots & \vdots \\ V_k & \cdots & 0 & \vdots & \vdots \\ V_q & \cdots & \cdots & \cdots & M_q \end{bmatrix}
$$

(33)

where $\lambda_1 = \mu(\overline{M}_{k1}) = \mu(\overline{M})$.

We partition the matrix as:

$$
\overline{V}_k = \{V_i \mid V_i \not\rightarrow V_k\} \quad (34)
$$

$$
\overline{V}_k = \{V_i \mid V_i \rightarrow V_k\} \quad (35)
$$
ordered as before. We can then create the matrix:

\[
\begin{bmatrix}
\vec{V}_k & V_k & \overline{V}_k \\
B_1 & \ddots & \mathbb{1} \\
D_1 & \mathbb{B}_p & D_3 \\
\mathbb{D}_2 & M_{k_1} & D_4 \\
\mathbb{D}_5 & M_{k_{1+1}} & \ddots \\
\vec{V}_k & V_k & \overline{V}_k \\
\end{bmatrix}.
\] (36)

To show that \( D_i = 0 \), for \( i=1,2,..,5 \), we proceed as follows:

Claim: \( D_1 = 0 \). Proof: The vertices are written in the same numerical order as in the matrix \( \overline{M} \), so there is no path from one node to a node that precedes it in the matrix \( \overline{M} \). □

Claim: \( D_2 = 0 \). Proof: If \( S_i \in V_k \), and \( S_j \in \vec{V}_k \), then a path from \( S_i \) to \( S_j \) would imply that \( S_j \) is in \( V_k \), which is not the case. □

Claim: \( D_3 = 0 \). Proof: There is no path from a node in \( \overline{V}_k \) to any node in \( V_k \). If there was a

one-step path from a node in \( \overline{V}_k \) to a node in \( \vec{V}_k \), then there would be a path that goes from that

to a node in \( V_k \), which can not happen, by definition of a node being in \( \overline{V}_k \). □

Claim: \( D_4 = 0 \). Proof: A node in \( \overline{V}_k \) cannot have a path to a node in \( V_k \), so it certainly cannot have

a one-step path to a node in \( V_k \). □

Claim: \( D_5 = 0 \). Proof: Reasoning similar to the proof that \( D_1 = 0 \). □

So we end with a matrix of the form:

\[
\begin{bmatrix}
\vec{V}_k & V_k & \overline{V}_k \\
\vec{V}_k & \begin{bmatrix} B_1 & \ddots \\ 0 & \mathbb{B}_p \\ 0 & \mathbb{D}_2 & M_{k_1} \\ 0 & 0 & M_{k_{1+1}} \\ 0 & 0 & \ddots \\ 0 & 0 & \mathbb{D}_5 & M_q \\
\end{bmatrix} \\
\vec{V}_k & V_k & \overline{V}_k \\
\end{bmatrix}.
\] (37)

which has the form: \( [A_1 \quad \mathbb{B}] \), where \( \lambda_1 = \mu(\overline{M}) = \mu(\overline{M}_{k_1}) \) which is in the lower right corner of \( A_1 \).

We then continue the same process with the matrix \( \mathbb{D} \) to arrive at the required form. □
Theorem 5.48. Suppose $\lambda$ is an eigenvalue of matrix $M$. There is at least one circuit in $G(M)$ whose average weight is $\lambda$.

Theorem 5.49.

1. For the matrix $\widetilde{M}$ in Theorem 5.47, $\lambda_1, \lambda_2, \ldots, \lambda_{k_0}$ are its eigenvalues. If $i_0$ is a node belonging to a circuit of average weight $\lambda_j$ then the $i_0^{th}$-row of $M_{\lambda_j}^+$ is an eigenvector of $\widetilde{M}$ that corresponds to $\lambda_j$.

2. $M$ has no other eigenvalue than $\lambda_1, \lambda_2, \ldots, \lambda_{k_0}$.

If $V_i$ and $V_j$ are classes then we say that $V_j$ has access to $V_i$ if either $i=j$ or there exists $u \in V_j$ and $v \in V_i$ such that there exists a path from $u$ to $v$ in $G(A)$. If $\mu(A_j) > \mu(A_i)$, then we say that class $V_j$ dominates $V_i$. The following theorem from [3] gives the condition for a (reducible) matrix to have an eigenvalue.

Theorem 5.50. Let $A \in \mathbb{M}_{n \times n}^+$, and suppose that $A$ is in Frobenius Normal Form. Then $\lambda$ is an eigenvalue of $A$ if and only if there exists an $i$ such that $\mu(A_i) = \lambda$ and no class that dominates $A_i$ has access to $A_i$.

Example 5.51. For a simple example, consider the matrices $A = \begin{bmatrix} 5 & 2 \\ \theta & 1 \end{bmatrix}$, and $B = \begin{bmatrix} 1 & 2 \\ \theta & 5 \end{bmatrix}$.

$A$ has one eigenvalue, $\lambda = 5$, with

$$\begin{bmatrix} 5 & 2 \\ \theta & 1 \end{bmatrix} \odot \begin{bmatrix} 1 \\ \theta \end{bmatrix} = 5 \odot \begin{bmatrix} 1 \\ \theta \end{bmatrix}$$

while $B$ has two eigenvalues, $\lambda_1 = 1$ and $\lambda_2 = 5$, with

$$\begin{bmatrix} 1 & 2 \\ \theta & 5 \end{bmatrix} \odot \begin{bmatrix} 1 \\ \theta \end{bmatrix} = 1 \odot \begin{bmatrix} 1 \\ \theta \end{bmatrix}$$

and

$$\begin{bmatrix} 1 & 2 \\ \theta & 5 \end{bmatrix} \odot \begin{bmatrix} 0 \\ 3 \end{bmatrix} = 5 \odot \begin{bmatrix} 0 \\ 3 \end{bmatrix}$$

This is the case since in matrix $A$, the class with 5 has access to the class with 1, whereas in matrix $B$, the maximum class with 5 does not have access to the class with 1.
**Theorem 5.52.** If \(A\) is irreducible, then there exists \(k \in \mathbb{N}\), and \(c \in \mathbb{N}\setminus\{0\}\), such that \(A^{k+c} = \lambda^c \otimes A^k\).

**Example 5.53.** \(A = \begin{bmatrix} \theta & 2 & \theta \\ \theta & \theta & 3 \\ 4 & \theta & \theta \end{bmatrix}\) 
\(\mu(A) = 3\)
With the help of Theorem 5.52, since \(A\) is irreducible, we note that \(A^4 = 3^2 \otimes A^1\).

**Example 5.54.**
\[
A = \begin{bmatrix} 1 & 3 & 2 & 1 \\ 2 & 3 & 3 & 1 \\ 0 & 0 & 3 & 1 \\ 2 & 1 & 9 & 1 \end{bmatrix}
\]
\(\mu(A) = 5\)
\(A^5 = A^{3+2} = 5^2 \otimes A^2\)

\[
A^3 = \begin{bmatrix} 10 & 10 & 13 & 11 \\ 10 & 10 & 13 & 11 \\ 10 & 10 & 13 & 11 \\ 12 & 12 & 19 & 13 \end{bmatrix}
\]
\(A^5 = \begin{bmatrix} 20 & 20 & 23 & 21 \\ 20 & 20 & 23 & 21 \\ 20 & 20 & 23 & 21 \\ 22 & 22 & 29 & 23 \end{bmatrix}\)

The following theorem illustrates a useful method to be used to calculate \(\mu(A)\).

**Theorem 5.55.** A formula for the maximum cycle mean \(\mu\) in the max-plus algebra notation is:
\[
\mu = \bigoplus_{j=1}^{n} \text{Trace}(A^j)^{(1/j)}
\]  \hspace{1cm} (38)

*Justification.* See [2] for more detail. Consider an \(n \times n\) matrix \(A\) with corresponding precedence graph \(G = (V,E)\). The maximum weight of all Circuits of length \(j\) which pass through node \(i\) of \(G\) can be written as \((A^j)_{ii}\). The maximum of these maximum weights over all nodes is \(\bigoplus_{i=1}^{n} (A^j)_{ii}\) which can be written \(\text{Trace}(A^j)\). The average weight is obtained by dividing this number by \(j\) in the usual algebra sense, but this can be written \((\text{Trace}(A^j))^{(1/j)}\) in the max-plus algebra notation. Finally, we have to take the maximum over all circuit lengths \(j\). It is not necessary to consider lengths larger than the number \(n\) of nodes since it is enough to limit ourselves to elementary circuits. Therefore we get the above formula.

The following theorem is due to Karp, and is included as an example of another method which can be used to calculate \(\mu(A)\) for a matrix in \(\mathfrak{M}^+\).
Theorem 5.56. Given an $n \times n$ matrix $A$, the maximum cycle mean is given by:
\[
\lambda = \max_{1 \leq i \leq n} \min_{0 \leq k \leq n-1} \frac{(A^n)_{ij} - (A^k)_{ij}}{n-k}, \forall j
\] (39)

5.4 Symmetrization of the Max-Plus Algebra

The Max-Plus algebra system lacks an additive inverse. Therefore some equations do not have a solution. For example, the equation $x \oplus 3 = 2$ has no solution since there is no number $x$ such that $\max(x, 3) = 2$. One way of trying to solve this problem is to embed the Max-Plus algebra into a larger system which will have an additive inverse. We would like to be able to solve the equation: $a \oplus x = \theta$, where $a \in \mathbb{M}^+$. This is known as symmetrizing $a$. The following proposition shows that this is impossible.

Proposition 5.57. Every idempotent group is reduced to the null element.

Proof. Assume that the group $(G, \oplus)$ is idempotent with additive identity $\theta$. Suppose that $b$ is the symmetric element of $a \in G$, i.e., $a \oplus b = \theta$. Then we have:
\[
a = a \oplus \theta = a \oplus (a \oplus b) = (a \oplus a) \oplus b = a \oplus b = \theta.
\]

Gaubert, [18], creates the $S_{\max}$ system to extend $\mathbb{M}^+$ to a system which include additive inverses. We give a brief overview of his technique. The technique presented there is a first attempt to symmetrize the Max-Plus Algebra system. This system is not as transparent as one would like. The basic operation used in this symmetrization is not transitive. One is able to get around this initial problem, but the result, although usable, is somewhat complicated. We present this material as a comparison to the method developed later in Section 8, where we are able to compute the solutions to equations in a manner which is considerably easier. The embedding here is a more difficult embedding.

The new system: $S_{\max}$

We attempt to extend the Max-Plus algebra to a larger system which will include an additive inverse in the same way that the natural numbers were extended to the larger system of integers. A thorough introduction and treatment of this symmetrization algebra is given in [18].

Note 5.58. We use the same symbols, $\oplus$ and $\otimes$, that were used in $\mathbb{M}^+$ because there is a natural correspondence between these "new" operations (on ordered pairs) and the original operations in $\mathbb{M}^+$. The context of the symbols should tell which system is being used in an unambiguous way.

Definition 5.59. We let $\mathcal{P} \overset{\text{def}}{=} \mathbb{M}^+ \times \mathbb{M}^+$.

Let $x = (x_1, x_2)$, and $y = (y_1, y_2)$, then we define the new operations on $\mathcal{P}$:
Definition 5.60. Let \( x,y \in \mathcal{P} \), then
\[
x \oplus y = (x_1, x_2) \oplus (y_1, y_2) \equiv (x_1 \oplus x_2, y_1 \oplus y_2)
\]
\[
x \otimes y = (x_1, x_2) \otimes (y_1, y_2) \equiv (x_1 \otimes y_1 \oplus x_2 \otimes y_2, x_1 \otimes y_2 \oplus x_2 \otimes y_1)
\]
Here we have \((\theta, \theta)\) is the additive identity, and \((e, \theta)\) is the unit element (multiplicative identity) of the set \( \mathcal{P} \).

Definition 5.61. Let \( x=(x_1, x_2) \), and define:

1. \( \ominus x \equiv (x_2, x_1) \).

2. The absolute value of \( x \): \( |x| = x_1 \oplus x_2 \equiv \max\{x_1, x_2\} \).

3. The balance operator: \( x^* = x \ominus x = (|x|, |x|) \).

It can be verified that \((\mathcal{P}, \oplus)\) is associative, commutative, and idempotent, with additive identity \((\theta, \theta)\); and \((\mathcal{P}, \otimes)\) is associative, commutative and distributive over \( \oplus \), and the multiplicative identity is \((e, \theta)\). The additive identity is absorbing under \( \ominus \). Therefore the algebraic structure \((\mathcal{P}, \oplus, \otimes)\) is a commutative dioid. We will call this the algebra of pairs.

We can also show that the following properties hold:

1. \( u^* = (\ominus u)^* = (u^*)^* \)

2. \( u \oplus v^* = (u \oplus v)^* \)

3. \( \ominus (\ominus u) = u \)

4. \( \ominus (u \oplus v) = (\ominus u) \oplus (\ominus v) \)

5. \( \ominus (u \otimes v) = (\ominus u) \otimes v = u \otimes (\ominus v) \)

In the conventional algebra, we have \( a - a = 0 \), but in the algebra of pairs, we have \( a \ominus a = a^* \neq (\theta, \theta) \) for all \( a \in \mathcal{P} \), unless \( a=(\theta, \theta) \). So we introduce a new relation on \( \mathcal{P} \):

Definition 5.62 (balance relation). Let \( x=(x_1, x_2) \) and \( y=(y_1, y_2) \). We say that \( x \) balances \( y \), written \( x \, \Delta \, y \), if and only if \( x_1 \oplus y_2 = x_2 \oplus y_1 \).

With this new relation, we have \( a \ominus a = a^* = (|a|, |a|) \, \Delta \, (\theta, \theta) \) for all \( a \in \mathcal{P} \). We would like to form the quotient set using this new relation, but the big caveat is that the balance relation is not transitive! For example: \( (3,2) \, \Delta \, (3,3) \), and \( (3,3) \, \Delta \, (2,3) \), but \( (3,2) \ntriangleq (2,3) \). Therefore, the balance relation is not an equivalence relation, and we cannot use it to form a quotient set. Therefore we define a new relation which is closely related to the balance operator, but that is transitive:

\[
(x_1, x_2) \, \mathcal{R} \, (y_1, y_2) \text{ if } \begin{cases} 
(x_1, x_2) \Delta (y_1, y_2) & \text{if } x_1 \neq x_2 \text{ and } y_1 \neq y_2, \\
(x_1, x_2) = (y_1, y_2) & \text{otherwise.}
\end{cases}
\]
This new relation is an equivalence relation on $\mathbb{P}$. So we define the quotient set $\mathbb{S} = \mathbb{P}/R$. The algebraic structure $\mathbb{S}_{\text{max}} = (\mathbb{S}, \oplus, \otimes)$ is called the symmetric max-plus algebra. The quotient set has three different types of equivalence classes:

- $\overline{(t, -\infty)} = \{(t, x) \in \mathbb{P} | x < t\}$, called max - positive;
- $\overline{(-\infty, t)} = \{(x, t) \in \mathbb{P} | x < t\}$, called max - negative;
- $\overline{(t, t)} = \{(t, t) \in \mathbb{P}\}$, called balanced.

We see that $\overline{(t, -\infty)}$ are associated with the elements of $\mathbb{R}$. Let $\mathbb{S}^\oplus$ = the max-positive elements, and $\mathbb{S}^\ominus$ = the max-negative elements, and $\mathbb{S}^\ast$ = the balanced elements. Also let $\mathbb{S}^\vee = \mathbb{S}^\oplus \cup \mathbb{S}^\ominus$. We call $\mathbb{S}^\vee$ the set of signed elements in $\mathbb{S}$. So we have $\mathbb{S} = \mathbb{S}^\oplus \cup \mathbb{S}^\ominus \cup \mathbb{S}^\ast$. Note that $\mathbb{S}^\oplus \cap \mathbb{S}^\ominus \cap \mathbb{S}^\ast = \{\theta, \overline{\theta}\}$, and $\theta = \ominus \theta = \theta^\ast$.

Example 5.63. \[2 \oplus (\ominus 3) = \overline{(2, -\infty)} \oplus \overline{(-\infty, 3)} = \overline{(2, 3)} = \overline{(-\infty, 3)} = \ominus 3\]

In general, if $a, b \in \mathbb{R}$, then we have:

- $a \oplus (\ominus b) = \begin{cases} a & \text{if } a > b \\ \ominus b & \text{if } b > a \end{cases}$
- $a \ominus a = a \oplus (\ominus a) = a^\ast$

The set $\mathbb{S}^\vee \setminus \{\theta\}$ is the set of invertible elements in $\mathbb{S}$.

The main algebraic features of balances are:

**Proposition 5.64.**

(i) $a \Delta a$ (reflexivity)

(ii) $a \Delta b \iff b \Delta a$ (symmetry)

(iii) $a \Delta b \iff a \ominus b \Delta \theta$

(iv) $a \Delta b, c \Delta d \implies a \oplus c \Delta b \oplus d$

(v) $a \Delta b \implies ac \Delta bc$

Although $\Delta$ is not transitive, we can manipulate balances in the cases where some variables are signed.

**Proposition 5.65 (Weak substitution).**

$$\begin{align*}
\begin{cases}
x \Delta a \\
c \Delta b
\end{cases} & \quad \text{and} \quad x \in \mathbb{S}^\vee \implies c a \Delta b
\end{align*}$$ (43)
Letting $c=e$ yields:

**Proposition 5.66 (Weak transitivity).**

\[ a \Delta x, \ x \Delta b, \text{ and } x \in S^\vee \implies a \Delta b \] (44)

There is one case in which we can translate balances into equations:

**Proposition 5.67 (Reduction of balances).**

$x \Delta y$, and both $x, y \in S^\vee \implies x = y$

We can give some extra properties of balances.

**Proposition 5.68.**

\[ \forall a,b,c \in S, \ a \odot c \Delta b \text{ if and only if } a \Delta b \odot c. \]

**Proposition 5.69.** \[ \forall a,b \in S^\vee, \ a \Delta b \implies a = b. \]

**Proposition 5.70.** If $x \in S$, then

(a) $x \odot b^* = (x \odot b)^*$

(b) $x \odot b^* = \begin{cases} x & \text{if } |x| > |b| \\ b^* & \text{if } |x| < |b| \end{cases}$

**Example 5.71.**

\[
3 \odot 2^* \odot 4 \odot 5 = 3 \odot (2 \odot 2) \odot 4 \odot 5 \\
= 3 \odot 2 \odot 2 \odot 4 \odot 5 \\
= 3 \odot 2 \odot 4 \odot 2 \odot 5 \\
= (3 \odot 2) \odot 4 \odot (2 \odot 5) \\
= 3 \odot 4 \odot (2 \odot 5) \\
= 4 \odot 5 \\
= \odot 5
\]

The balance operation can be extended to vectors and matrices by applying the balance operator elementwise.

**Proposition 5.72.** For all $A,B,C \in S^{m \times n}$, $A \odot C \Delta B$ if and only if $A \Delta B \odot C$.

**Proposition 5.73.** For all $A,B \in (S^\vee)^{m \times n}$, $A \Delta B \implies A = B$. 

38
Equations to Balances

Consider the equation in \( \mathbb{R}_{\text{max}} \):

\[
Ax \oplus b = Cx \oplus d
\]  

(45)

in \( \mathbb{R}_{\text{max}} \). We can rewrite equation (45) in \( S_{\text{max}} \) as:

\[
Ax \oplus b \Delta Cx \oplus d
\]  

(46)

by reflexivity, and by the previous properties as:

\[
(A \ominus C)x \oplus (b \ominus d) \Delta \theta
\]  

(47)

We would like to solve some equations or balances when one of the elements is an element of \( S^\uparrow \). To this end we have one lemma.

**Lemma 5.74.** Suppose \( d \in S^\ast \), \( p = b \ominus d \implies p \Delta b \).

**Proof.** Let \( p = (p_1,p_2), b = (b_1,b_2), d = (g,g) \), where \( g = |d| \). If \( (p_1,p_2) = (b_1,b_2) \ominus (g,g) \), then \( p_1 = b_1 \ominus g \), and \( p_2 = b_2 \ominus g \). To show that \( p \Delta b \) we must show that \( p_1 \ominus b_2 = p_2 \ominus b_1 \). So suppose that \( p_1 \ominus b_2 \neq p_2 \ominus b_1 \), but by substitution, we get \( b_1 \ominus g \ominus b_2 \neq b_2 \ominus g \ominus b_1 \), which is a contradiction. Therefore, \( p \Delta b \). \( \square \)

Lemma 5.74 allows us to remove a balanced element from an equation if we allow the equation to become a balance.

The following are some of the basic properties of \( S \).

**Proposition 5.75.** If \( a,b \in S \) and \( d^\ast,g^\ast \in S^\ast \), then

(a) If \( a \Delta \theta \), and \( a \in S^\uparrow \), then \( a = \theta \).

(b) If \( a \Delta \theta \), then \( a \Delta d^\ast \).

(c) \( b \Delta d^\ast \neq b \Delta \theta \).

(d) \( a \Delta d^\ast \), and \( |a| > |d^\ast| \), then \( a \in S^\ast \).

(e) \( a^\ast = (\ominus d)^\ast = (d^\ast)^\ast \)

(f) \( (\ominus a) \ominus (\ominus b) = a \ominus b \).

(g) \( a \ominus a^\ast = (a \ominus d)^\ast \).

(h) \( \ominus (\ominus a) = a \).
(i) \( \ominus (a \oplus b) = (\ominus a) \oplus (\ominus b) \).

(j) \( \ominus (a \otimes b) = (\ominus a) \otimes b = a \otimes (\ominus b) \).

(k) \( d^* \otimes g^* = (d \otimes g)^* \).

(l) \( a \otimes d^* = a \otimes d^* \).

(m) \( a^* \otimes g^* = (d \otimes g)^* \).

(n) \( a^* \otimes g^* = d^* \otimes g^* = (d \otimes g)^* \).

(o) \( a \oplus a^* = \begin{cases} a & \text{if } |a| > |d^*| \\ d^* & \text{if } |a| \leq |d^*| \end{cases} \).

(p) \( a^* \otimes a = \begin{cases} \ominus a & \text{if } |a| > |d^*| \\ d^* & \text{if } |a| \leq |d^*| \end{cases} \).

**Proposition 5.76.** The set of solutions of the general linear system (45) in \( \mathbb{R}_{\max} \) and the set of positive solutions of the associated linear balance (47) in \( S \) coincide.

*Proof.* See [24]. \( \square \)

**The scalar linear balance**

**Theorem 5.77.** Let \( a \in S^\setminus\{\theta\} \) and \( b \in S^\setminus \), then the balance

\[ ax \oplus b \Delta \theta \]

has the unique signed solution: \( x^b = \ominus a^{-1}b \).

*Proof.* See [24]. \( \square \)

**Note 5.78.** Non-trivial linear balances always have solutions in \( S \), that is why \( S \) may be considered as a linear closure of \( \mathbb{R}_{\max} \).

**Note 5.79.** We can describe all the solutions of (48). For all \( t \in \mathbb{R}_{\max} \), we have obviously \( at^* \Delta \theta \). Adding this balance to \( ax^b \oplus b \Delta \theta \), we get \( a(x^b \oplus t^* ) \oplus b \Delta \theta \). Thus,

\[ x_t = x^b \oplus t^* \] (49)

is a solution to (48). If \( t \geq |x^b| \), then \( x_t = b^* \) is balanced. Conversely, it can be checked that every solution of (48) may be written as in (49). The unique signed solution \( x^b \) is also the least solution.
**Note 5.80.** If $b \notin S^\top$, we lose uniqueness of signed solutions. Every $x$ such that $|ax| \leq |b|$ (i.e. $|x| \leq |a^{-1}b|$) is a solution of balance (48).

**Note 5.81.** If $a \notin S^\top$, we again lose uniqueness. Assume $b \in S^\top$ (otherwise, the balance holds for all value of $x$), then every $x$ such that $|ax| \geq |b|$ is a solution.

**Determinants in Symmetrized Algebra**

**Definition 5.82 (Max-algebraic signature).** If $\sigma$ is a permutation, then the max-algebraic signature of $\sigma$ is defined as:

$$
\text{sgn}(\sigma) = \begin{cases} 
eq & \text{if } \sigma \text{ is even} \\ \ominus \neq & \text{if } \sigma \text{ is odd} 
\end{cases}
$$

**Definition 5.83 (Max-algebraic determinant).** Consider a matrix $A \in S^{n \times n}$.

The max-algebraic determinant of $A$ is defined as:

$$
det(A) = \bigoplus_{\sigma \in \mathfrak{S}} \text{sgn}(\sigma) \otimes \bigotimes_{i=1}^{n} a_{i\sigma(i)}
$$

**Note 5.84.** As in the conventional algebra system, if $\alpha \in S$ and $A \in S^{n \times n}$ then $\det(A^T) = \det(A)$, and $\det(\alpha \otimes A) = \alpha^n \otimes \det(A)$. 

41
To illustrate the use of definition 5.83, we include the following example.

**Example 5.85.** Find the determinant of \( A = \begin{pmatrix} 2 & 1 & 3^* \\ 1 & \theta & 2 \\ 3^* & 2 & 5 \end{pmatrix} \)

\[
\begin{vmatrix} 2 & 1 & 3^* \\ 1 & \theta & 2 \\ 3^* & 2 & 5 \end{vmatrix} = 2 \circ \begin{vmatrix} \theta & 2 \\ 2 & 5 \end{vmatrix} = 2 \circ (\theta \circ (5 \circ 2 \circ 2)) \\
= 2 \circ (\theta \circ (\theta \circ (1 \circ 5 \circ 2 \circ 3^*)) \\
= 2 \circ (\theta \circ (\theta \circ (1 \circ 2 \circ 3^* \circ \theta)) \\
= 2 \circ (\theta \circ 4) \circ (\theta \circ (6 \circ 5^*) \circ (3^* \circ (3 \circ \theta)) \\
= 2 \circ (\theta \circ 4) \circ (\theta \circ (6 \circ 3^* \circ (3 \circ \theta)) \\
= (\theta \circ 6) \circ (\theta \circ (6 \circ 3^* \circ (3 \circ \theta)) \\
= (\theta \circ 6) \circ (\theta \circ (6 \circ 6) \\
= 6 \circ (6 \circ 6) \\
= 6 \circ 7 \\
= \oplus 7
\]

\[\blacksquare\]

**Theorem 5.86 (Cramer system).** Let \( A \) be an \( n \times n \) matrix with entries in \( S_{\text{max}} \), and \( b \in (S_{\text{max}}^n) \). Then every signed solution of

\[ Ax \Delta b \quad (52) \]

satisfies

\[ \det A \cdot x \Delta A^{\text{adj}} b. \quad (53) \]

Conversely, assume that \( A^{\text{adj}} b \) is signed and \( \det(A) \) is invertible, then the “Cramer solution” \( x^b = \det(A)^{-1} A^{\text{adj}} b \) is the unique signed solution of (52).

The following example is included from [24, page 155]. We will work this example again after studying msets as a comparisons of the two methods, see Example 8.95.
Example 5.87. Find the solutions of:

\[
\begin{align*}
\max(x, y - 4, 1) &= \max(x - 1, y + 1, 2) \\
\max(x + 3, y + 2, -5) &= \max(y + 2, 7)
\end{align*}
\]  \hspace{1cm} (54)

This can be written in matrix form as:

\[
\begin{bmatrix}
0 & -4 \\
3 & 2
\end{bmatrix} \otimes \begin{bmatrix} x \\ y \end{bmatrix} \oplus \begin{bmatrix} 1 \\ -5 \end{bmatrix} = \begin{bmatrix} -1 & 1 \\ -\infty & 2 \end{bmatrix} \otimes \begin{bmatrix} x \\ y \end{bmatrix} \oplus \begin{bmatrix} 2 \\ 7 \end{bmatrix}
\]  \hspace{1cm} (55)

The balance corresponding the equation (55) is

\[
\begin{bmatrix}
0 & \ominus 1 \\
3 & 2 \star
\end{bmatrix} \otimes \begin{bmatrix} x \\ y \end{bmatrix} \Delta \begin{bmatrix} 2 \\ 7 \end{bmatrix}
\]  \hspace{1cm} (56)

The \( \det(A) = 4 \), which is invertible.

\[
D_x = \begin{vmatrix} 2 & 1 \\ 7 & 2 \star \end{vmatrix} = 8, \quad D_y = \begin{vmatrix} 0 & 3 \\ 2 & 7 \end{vmatrix} = 7
\]

\[
A^{\text{adj}}b = \begin{bmatrix} D_x \\ D_y \end{bmatrix} = \begin{bmatrix} 8 \\ 7 \end{bmatrix} \in (S^\vee)^2
\]

So, \( x = \frac{D_x}{D_y} = 8 - 4 = 4 \), and \( y = \frac{D_y}{D_x} = 7 - 4 = 3 \) gives the unique positive solution in \( S_{\text{max}} \) of Equation (56). Thus it is the unique solution of Equation (54) in \( S_{\text{max}} \).
6 Max-Times Algebra

6.1 Basics

In the previous sections, we have been working within the Max-Plus Algebra system. All of the results in the Max-Plus Algebra system have analogs to corresponding theorems in the Max-Times Algebra. Many new results, and easier proofs, can be developed using this particular Path Algebra. The Max-Times algebra is closer to the conventional system of non-negative matrices, and thus easier to manipulate. The notation $\mathbb{R}^+$ will be used for the nonnegative real numbers.

We begin with a definition of the Max-Times algebra.

**Definition 6.1.** Let $\mathbb{R}^+$ represent the nonnegative number and define

(i) $a \boxplus b = \max(a,b)$, where $a, b \in \mathbb{R}^+$.

(ii) $a \boxtimes b = a \cdot b$ (The usual multiplication).

**Note 6.2.** We use the notation $\mathfrak{M}^*$ for the algebraic system $(\mathbb{R}^+, \boxplus, \boxtimes)$.

**Definition 6.3.** If $A, B \in \mathfrak{M}^*_{n \times n}$, then $\boxplus$ and $\boxtimes$ are extended to matrices as

(i) $[A \boxplus B]_{ij} = \max(a_{ij}, b_{ij})$.

(ii) $[A \boxtimes B]_{ij} = \max_{1 \leq k \leq n} \{a_{ik} \cdot b_{kj}\}$

There is an isomorphism between the Max-Plus Algebra and the Max-Times Algebra: $\varphi : \mathfrak{M}^+ \longrightarrow \mathfrak{M}^*$, which is defined as

(i) $\varphi(x) = e^x$, for all $x \in \mathbb{R}$, with $\varphi(-\infty) = 0$,

(ii) $\varphi^{-1}(y) = \ln(y)$ for all $y \in \mathbb{R}_{\geq 0}$, with $\varphi^{-1}(0) = -\infty$.

For matrices, the isomorphism is defined elementwise as $[\varphi(A)]_{ij} = [e^{a_{ij}}]$.

To verify that this is an isomorphism, we note that:

(i) $\varphi(a \oplus b) = e^{\max(a,b)} = e^{\max(a,b)} = \max(e^a, e^b) = e^{a \boxplus b} = \varphi(a) \boxplus \varphi(b)$.

(ii) $\varphi(a \odot b) = e^{a \cdot b} = e^{a \odot b} = \varphi(a) \boxtimes \varphi(b)$

With this isomorphism it follows that $A \odot B = \varphi^{-1}(\varphi(A) \boxtimes \varphi(B))$. 

44
**Definition 6.4.** Given a cycle in \( G(A) \), we define, analogous to the Max-Plus definition, the maximum geometric circuit mean as:

\[
\nu(A) = \max_{\gamma \in G(A)} \left( \prod_{(i,j) \in \gamma} a_{i,j} \right)
\]

(57)

With this definition of \( \nu(A) \), and the previous definition of \( \mu(A) \), it can be seen that \( \mu(A) = \varphi^{-1}(\nu(\varphi(A))) \), which we may write as \( \nu(\varphi(A)) = e^{\mu(A)} \).

As in the case of the Max-Plus Algebra we only need to consider cycles in our calculations of the maximum cycle means. This is the analog of Lemma 5.12 in the Max-Plus Algebra. We present this theorem for later use.

**Lemma 6.5.** If \( a,b \geq 0 \), and \( m,n>0 \), then \( \max\{a^{1/m},b^{1/n},(ab)^{1/(m+n)}\} = \max\{a^{1/m},b^{1/n}\} \)

**Proof.** Suppose, without loss of generality, that \( a^{1/m} \geq b^{1/n} \), then

\[
a^{1/m} \geq b^{1/n} \iff a^n \geq b^m \iff a^m a^n \geq a^m b^m \\
\iff a^{m+n} \geq (ab)^m \iff a^{m/n} \geq (ab)^{1/n}
\]

\(\square\)

We now give some of the basic results in the Max-Times algebra, and add proofs for completeness.

**Proposition 6.6.** Let \( A, B \in \mathfrak{M}_{n \times n}^* \), and \( \alpha \in \mathfrak{M}^* \) then:

(i) If \( \alpha \) is a scalar, then \( \alpha \boxtimes A = \alpha \cdot A \).

where \([\alpha \cdot A]_{ij} \equiv \alpha \cdot A_{ij}\)

Therefore, we will only write \( \alpha A \) instead of \( \alpha \boxtimes A \).

(ii) If \( A \) has only one positive element in each row, then \( A \boxtimes B = A \cdot B \).

(iii) If \( B \) has only one positive element in each column, then \( A \boxtimes B = A \cdot B \).

(iv) If \( P \) is a permutation matrix then \( P \boxtimes A \boxtimes P^T = P \cdot A \cdot P^T \).

(v) If \( D = \text{diag}(a_{11}, a_{22}, \ldots, a_{nn}) \), where each element \( a_{ii} \) is nonzero, then \( D^{-1} \) exists in the Max-Times Algebra, and \( D^{-1} = \text{diag}\left(\frac{1}{a_{11}}, \frac{1}{a_{22}}, \ldots, \frac{1}{a_{nn}}\right) \).

(vi) If \( D \) is a diagonal matrix in \( \mathfrak{M}_{n \times n}^* \), and \( d_{ii} > 0 \), then \( D \boxtimes A \boxtimes D^{-1} = D \cdot A \cdot D^{-1} \).
(vii) If \( A = [a_{ij}] \) is a matrix with one nonzero element in each row and one nonzero element in each column, then \( A^{-1} \) exists in \( \mathfrak{M}^* \), and \( (A^{-1})_{ij} = \begin{cases} \frac{1}{a_{ji}} & \text{if } a_{ij} \neq 0 \\ 0 & \text{otherwise} \end{cases} \)

(viii) If \( P \) is a permutation matrix then \( P^{-1} \) exists in the Max-Times Algebra, and \( P^{-1} = P^T \).

(ix) \( A \boxtimes B \leq A \cdot B \leq n \cdot (A \boxtimes B) \).

(x) \( A_1 \boxtimes A_2 \boxtimes \cdots \boxtimes A_k \leq A_1 \cdot A_2 \cdot \cdots \cdot A_k \leq n^{k-1} (A_1 \boxtimes A_2 \boxtimes \cdots \boxtimes A_k) \).

(xi) \( A^\boxtimes_k \leq A_k \leq n^{k-1} A^\boxtimes_k \).

(xii) \( \frac{A^\boxtimes_k}{n^k} \leq A \leq n^{k-1} A^\boxtimes_k \).

(xiii) There exists \( k \) such that \( A^k > 0 \iff \text{there exists } m \text{ such that } A^\boxtimes_m > 0 \).

\textbf{Proof.}

(i) This result is obvious since calculations are element-wise.

(ii) Consider \( [A \boxtimes B]_{ij} = \max_k (A_{ik} B_{kj}) \). Since all elements of row \( i \) in \( A \) are zero except for one, then the sum (max) has only one nonzero product.

(iii) Same as (ii) except that \( B_{jk} \) has only one nonzero element in each column.

(iv) Corollary of (ii) and (iii).

(v) This is obvious as it can be seen that \( DD^{-1} = I \).

(vi) Corollary of (ii) and (iii).

(vii) It can be checked that \( A A^{-1} = I \).

(viii) Corollary of (vii).

(ix) \[
[A \boxtimes B]_{ij} = \max_k (A_{ik} \boxtimes B_{kj}) \\
\leq \sum_k (A_{ik} B_{kj}) \\
\leq n \cdot (\max_j (A_{ik} \cdot B_{kj})) \\
= n \cdot (A \boxtimes B)
\]

(x) Use induction with (ix).

(xi) Corollary of (x).

(xii) Corollary of (xi).

(xiii) Follows from (xii).

\[
0 < A^\boxtimes_m \leq A^m
\]
and \[ 0 < \frac{A^k}{n^{5_k}} \leq \frac{A^{E_k}}{n^{5_k}} \] \hspace{1cm} (60) \]

\[ \square \]

The results from the Max-Plus Algebra carry over to the Max-Times Algebra through the isomorphism. In particular we mention the following theorem.

**Theorem 6.7.** If \( A \) is irreducible, then \( \nu(A) \) is only eigenvalue of \( A \) and every eigenvector corresponding to \( \nu(A) \) is positive.
6.2 Spectral Radius of $A$ and the
Maximum Geometric Mean of $A$

Suppose $M \in \mathbb{R}^+_{n\times n}$. We use the following two definitions in this section.

$\rho(M)$ = the spectral radius of $M$ (in the conventional algebra sense).

$\nu(M)$ = the max geometric mean of all circuits in $G(M)$.

$$\nu(M) = \max_{\gamma \in G(A)} \left( \prod_{(i,j) \in \gamma} m_{ij} \right)^{1/|\gamma|} \quad (61)$$

This $\nu(M)$ is the definition of the maximum circuit mean used in the Max-Plus algebra translated to the Max-Times algebra. We have found that $\mu(M)$ is an eigenvalue of $M$ in the max-plus algebra. This also carries over to the max-times algebra system in an analogous manner. The question that arises is when, in the conventional algebra, are the two definitions equivalent; i.e. when is the maximum geometric mean of the circuits of a graph equal to the maximum eigenvalue of the adjacency matrix of the graph. The aim of this section is to give a necessary and sufficient condition for the maximum geometric mean of a nonnegative matrix to equal the maximum eigenvalue of the matrix.

We begin with the following theorem.

**Theorem 6.8.** Let $A_{n \times n} \in \mathbb{R}^+_{n \times n}$. Then $\rho(A) \geq \nu(A)$.

**Proof.** Suppose that $A \geq \mathbb{R}^+_{n \times n}$. If $A$ has no cycles then $A$ is nilpotent and 0 is only eigenvalue. So $\rho=0=\nu$.

So assume that $A$ has cycles. There exists a cycle, say $S_1 \rightarrow S_2 \rightarrow \cdots \rightarrow S_t \rightarrow S_1$. $\rho > 0$, and $\nu(A)>0$.

$$A \mathbf{x} = \rho \mathbf{x} \implies \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1t} \\ a_{21} & a_{22} & \cdots & a_{2t} \\ \vdots & \vdots & \ddots & \vdots \\ a_{t1} & a_{t2} & \cdots & a_{tt} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_t \end{bmatrix} = \rho \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_t \end{bmatrix} \quad (62)$$

$$\rho x_1 = a_{11}x_1 + a_{12}x_2 + \cdots + a_{1t}x_t \geq a_{12}x_2$$

$$\rho x_2 = a_{21}x_1 + a_{22}x_2 + \cdots + a_{2t}x_t \geq a_{23}x_3$$

$$\vdots \vdots$$

$$\rho x_t = a_{t1}x_1 + a_{t2}x_2 + \cdots + a_{tt}x_t \geq a_{tt}x_1$$

$$\rho^t( x_1 x_2 \cdots x_t ) \geq ( a_{12} a_{23} \cdots a_{tt} ) ( x_1 x_2 \cdots x_t )$$

$$\rho \geq (w(\gamma))^{1/t} = \overline{w(\gamma)} = \nu(A)$$
Therefore \( \rho(A) \geq \nu(A) \).

We see from this theorem that it must be a special matrix which satisfies the conditions. With this theorem complete, we may ask the following question: When is \( \rho(A) = \nu(A) \)? We will answer this question by finding the necessary and sufficient conditions for \( \rho(A) = \nu(A) \). We begin with a sufficient condition.

**Theorem 6.9 (Sufficient condition).**

\[
\begin{bmatrix}
0 & \cdots & 0 & 0 & + \\
+ & 0 & \cdots & \cdots & 0 \\
0 & + & \cdots & \cdots & \cdots \\
\vdots & \vdots & \ddots & \ddots & \ddots \\
0 & \cdots & \cdots & + & 0 \\
0 & \cdots & 0 & + & 0
\end{bmatrix}
\]

If \( A \approx_{\text{per}} \), then \( \rho(A) = \nu(A) \).

**Proof.**

\[
\Delta_A (\lambda) = \begin{vmatrix}
\lambda & 0 & 0 & 0 & -a_{12} \\
-\lambda & \lambda & 0 & 0 & \cdots \\
0 & -a_{32} & \ddots & \ddots & \ddots \\
\vdots & \vdots & \ddots & \ddots & \ddots \\
0 & 0 & \cdots & -a_{n-1, n-1} & \lambda
\end{vmatrix} = \lambda^n - \omega(\gamma)
\]

and \( \lambda^n - \omega(\gamma) = 0 \implies \lambda = \omega(\gamma)^{(1/n)} = \omega(\gamma) \).

So we see from Theorem 6.9 that if \( A \) is a matrix whose graph contains exactly one cycle, then \( \rho(A) = \nu(A) \). In order to investigate the necessary condition for \( \rho(A) = \nu(A) \), we need a few facts and lemmas from linear algebra.

**Fact 6.10.** Suppose that \( A \geq 0 \), and irreducible. Suppose that the cycle index of \( A \) is \( k \), which is the greatest common divisor of the lengths of all cycles of \( A \). Then we can permute the rows and columns of \( A \) to get a matrix in the form:

\[
M = \begin{bmatrix}
0_{c_1 \times c_1} & \cdots & \cdots & \cdots & M_1 \\
M_h & 0_{c_2 \times c_2} & \vdots & \vdots & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \ddots \\
M_{n-1} & 0_{c_{n-1} \times c_{n-1}} & \cdots & \cdots & M_2 \\
\cdots & \cdots & \cdots & M_2 & 0_{c_n \times c_n}
\end{bmatrix},
\]

which we usually write as

\[
M = \begin{bmatrix}
0 & \cdots & \cdots & \cdots & M_1 \\
M_h & 0 & \cdots & \cdots & \cdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \ddots \\
m_{n-1} & 0_{c_{n-1}} & \cdots & \cdots & M_2 \\
0 & \cdots & M_2 & 0
\end{bmatrix}
\]

49
or just as \( M = \begin{bmatrix} M_h & M_1 \\ \cdot & \cdot \\ M_3 & M_2 \end{bmatrix} \).

**Fact 6.11.** Suppose \( M = \begin{bmatrix} M_h & M_1 \\ \cdot & \cdot \\ M_3 & M_2 \end{bmatrix} \), then \( M^h = \begin{bmatrix} B_1 & \cdot \\ \cdot & \cdot \\ \cdot & B_h \end{bmatrix} \), where

\[
B_1 = A_1 A_2 \cdots A_h
\]

and

\[
B_j = A_j A_{j+1} \cdots A_h A_1 \cdots A_{j-1}
\]

(63)

(64)

**Fact 6.12.** \( \rho \left( M^h \right) = \rho \left( A_1 A_2 \cdots A_h \right) \)

**Fact 6.13.** \( \rho \left( M^h \right) = \left[ \rho \left( M \right) \right]^h \).

**Proof.** \( M x = \lambda x \implies M^k x = \lambda M^{k-1} x = \cdots = \lambda^k x \implies \lambda^k \) is an eigenvalue of \( M^k \).

**Fact 6.14.**

\[
(A_1 A_2 \cdots A_h)_{ij} = \sum_{k_1} \sum_{k_2} \cdots \sum_{k_{h-1}} (a_{ik_1} a_{k_1 k_2} \cdots a_{k_{h-1} i})
\]

(65)

Each product in the sum represents the product of the weights of the arcs of a path of length \( h \) from \( S_i \) to \( S_j \). So, this represents the sum of all the path-products of length \( h \) from \( S_i \) to \( S_j \).

The following facts from linear algebra will help with our investigation.

**Fact 6.15.** \( \rho(A) \geq a_{ii} \), for all \( 1 \leq i \leq n \).

**Proof.** See [17].

\[
\rho = \max_{x \geq 0} \min_{1 \leq i \leq n} \frac{(Ax)_i}{x_i}
\]

Letting \( x_i = e_i \), we get \( \rho \geq e_i^T A e_i = A_{ii} \)

Suppose that the matrix \( M \) is a matrix which contains at least one cycle. Let \( \tau \) be a critical cycle in \( G(M) \), and suppose, without loss of generality, that \( \tau \) contains the node \( S_1 \).
Theorem 6.16. \((\rho(M))^k \geq \) any one circuit-product through \(S_i\) of length=h, say \(\tau\)

\[
(\rho(M))^k = \rho(M^k) = \rho(A_1 A_2 \cdots A_h) \\
\geq (A_1 A_2 \cdots A_h)_{ii} \\
= \sum_{k_1} \sum_{k_2} \cdots \sum_{k_{h-1}} (A_{i_1 k_1} A_{i_2 k_2} \cdots A_{i_{h-1} k_{h-1}}) \\
= \sum_i \sum_{c_i} \sum_{1 \leq i \leq h-1} c_i \leq \sum_i M_{i_1} M_{i_2} \cdots M_{i_{h-1}} \\
\geq \text{any one circuit-product through } S_i \text{ of length=h, say } \tau
\]

Theorem 6.17 (Theorem 2). The length of \(\tau\) must be h.

Proof. Since h=greatest common divisor of the circuit length of all circuits in \(G(M)\), then all circuits
lengths must be a multiple of h. Suppose that the length of \(\tau\), (one of the) maximal circuits, is d·h.

Then \(M^d = (A_1 \cdots A_h A_1 \cdots A_h)^d = (A_1 \cdots A_h)^d\), and

\((A_1 \cdots A_h)_1 = \sum_{j_1, \ldots, j_{dh}} (a_{j_1} \cdots a_{j_{dh}} a_{1k_1}, \cdots) = \sum (\text{all d·h circuit products from } S_i \text{ to } S_i) = \text{maximal circuit product}.

Therefore, all d·h circuit products must be equal to zero, except for the circuit product

Corresponding to \(\tau\).

Claim. The maximal circuit cannot be an h-circuit repeated d times.

Proof of Claim. If \(\tau\) were an h-circuit from \(S_i\) to \(S_i\) and \(\gamma\) was the circuit \(\tau\) circuit repeated d
times, then \(w(\tau) = w(\gamma)\), because \(\prod_{\gamma} (A_1 \cdots A_h)^{(1/h)} = (\prod_{\gamma} (A_1 \cdots A_h)^d)^{(1/(dh))}\). So, if \(\gamma\) is

a dh-circuit which leads to the maximum product, then \(\tau\) is an h-circuit with the same maximum
geometric mean. Therefore in the \(\sum (\cdots)\), there would be the dh-circuit product and the h-circuit

product repeated d times.

Hence, \(\sum (\cdots) > \text{maximal circuit product, which can not occur.}\)

And we see that the maximal circuit must be of length=h.

The same reasoning as above gives that the maximal circuit also can not be a k-h-circuit

for any \(k < d\).

Therefore, the length of \(\tau\) must be h.

Lemma 6.18. If \(h \mid k\), then \(\nu(M^k) \geq (\nu(M))^k\)
Proof. If \( \tau \) is the circuit of \( M \) which has the maximum circuit product, then in \( M^k \), \( \tau \) would be repeated ("traced") \( k \) times. If the geometric mean of the \( \tau \)-circuit is equal to \( \lambda \), then the geometric mean of the repeated \( \tau \)-circuit would be \( \lambda^k \). So the maximum geometric mean of any cycle in \( M^k \) is at least \( \lambda^k \). It is possible that the maximum geometric mean may increase.

Suppose that \( \rho(M) = \nu(M) \), then \( (\rho(M))^k = (\nu(M))^k \) and we can conclude:

\[
(\rho(M))^k = \rho(M^k) = \rho(A_1 A_2 \cdots A_h)
\geq (A_1 A_2 \cdots A_h)_{ii}
= \sum_{k_1} \sum_{k_2} \cdots \sum_{k_{h-1}} (A_{ik_1} A_{ik_2} \cdots A_{ik_{h-1}})
\geq \text{the maximal circuit product}
= \nu(M^k)
\geq (\nu(M))^k
= (\nu(M))^k
\]

So, all the quantities in the list above must be equal.

We need a couple of more lemmas from linear algebra.

**Fact 6.19.** If \( A \geq 0 \) and \( \varepsilon \geq 0 \), then \( \rho(A + \varepsilon) \geq \rho(A) \).

**Fact 6.20.** If \( A \geq 0 \), and irreducible, and \( B \geq A \), then \( \rho(B) > \rho(A) \).

So, suppose that the \( A_i \) (\( i = 1, 2, \ldots, h \)) blocks are larger than 1x1 and irreducible. Set

\[
N = \begin{bmatrix}
a_h \\
a_{h-1} \\
\vdots \\
a_2
\end{bmatrix}
\]

\[
\begin{bmatrix}
a_1
\end{bmatrix}
\]

We have \( M \geq N \), and \( \nu(M) = \rho(M) > \rho(N) = \nu(M) \). This is a contradiction.

Hence, each of the \( A_i \) (\( i = 1, 2, \ldots, h \)) blocks must be of size 1x1.

Therefore, if \( \rho(A) = \nu(A) \), then \( A \) must be similar to a matrix with only one cycle.
\[
A \approx_{\text{per}} \begin{bmatrix}
0 & \cdots & \cdots & \cdots & 0 & + \\
+ & 0 & \cdots & \cdots & \cdots & 0 \\
0 & + & \ddots & \ddots & \ddots & \vdots \\
: & : & \ddots & \ddots & \ddots & \vdots \\
: & \cdots & \cdots & + & 0 & 0 \\
0 & \cdots & \cdots & 0 & + & 0
\end{bmatrix}
\]

We have now proven the following Theorem.

\textbf{Theorem 6.21.} \( \rho(A) = \mu(A) \) if and only if \( A \approx_{\text{per}} \)

\[
\begin{bmatrix}
0 & \cdots & \cdots & \cdots & 0 & + \\
+ & 0 & \cdots & \cdots & \cdots & 0 \\
0 & + & \ddots & \ddots & \ddots & \vdots \\
: & : & \ddots & \ddots & \ddots & \vdots \\
: & \cdots & \cdots & + & 0 & 0 \\
0 & \cdots & \cdots & 0 & + & 0
\end{bmatrix}
\]

Theorem 6.21, above, states that the Necessary and Sufficient condition for \( \rho(A) = \nu(A) \) is that \( G(A) \) consists of exactly one cycle. We include the following example to illustrate this equality.

\textbf{Example 6.22.}

\[
A = \begin{bmatrix}
0 & 0 & 0 & 4 \\
1 & 0 & 0 & 0 \\
0 & 2 & 0 & 0 \\
0 & 0 & 2 & 0
\end{bmatrix} \in \mathbb{R}^{4 \times 4}
\]

\[
|\lambda I - A| = \lambda^4 - 16
\]

\[
\rho(A) = \sqrt{16} = 4
\]

\[
\mu(A) = \left( \prod_{(i,j) \in \gamma_0} a_{ij} \right)^{1/(\ell(\gamma_0))}
\]

\[
\mu(A) = (1 \cdot 2 \cdot 2 \cdot 4)^{\frac{1}{4}} = \sqrt{16} = 4
\]

Here, according to Theorem 6.21, \( \mu(A) = \rho(A) \)
7 Cancellative Semirings

As we recall a cancellative semiring is one which obeys the additional axiom that if \(a+b=a+c\) then \(a=c\). Our aim in studying Cancellative semirings is to generalize the theory of rings. We investigate the embedding theorems in this section. This will allow us to prove identities in Semirings which are analogous to theorems in rings. In particular we will look at the identities involving the Adjoint and the Determinant, which will allow us to solve problems in linear algebra using an analogy of Cramer’s Rule.

We begin by discussing the Embeddings of Semirings into a “ring of Differences.”

7.1 Embeddings and Morphisms of Semirings

What we would like to do is to embed the semiring, \(S\), into a ring, \(R\), such that \(R\) has a subset, \(S'\), which is a semiring isomorphic to \(S\).

This is not possible in general, but if \(S\) is a cancellative semiring with no zero divisors, then it is possible.

Golan, [20], contains the following two propositions.

**Proposition 7.1.** If \(S_1\) is a semiring, then there exists a cancellative semiring, \(S\), and a surjective morphism from \(S\) to \(S_1\).

**Proposition 7.2.** If \(S\) is a commutative, cancellative semiring, then \(S\) is isomorphic to a subsemiring, \(S_2\), of a ring, \(R^D=\text{“ring of differences,”}\) such that every element of \(R^D\) is the difference between two elements in the image of \(S\).

**Proof.** We include the construction of the Ring of Differences. Suppose that \((S,+,\cdot)\) is a commutative, cancellative semiring. Form \(S^2 = S \times S\), and consider \((S^2, \oplus, \odot)\) defined by:

**Definition 7.3.** If \((r,s), (r_1,s_1) \in S^2\), then

(a) \((r,s) \oplus (r_1,s_1) \equiv (r+r_1, s+s_1)\)

(b) \((r,s) \odot (r_1,s_1) \equiv (rr_1+ss_1, rs_1+sr_1)\)

It can be checked that \(S^2\) is indeed a commutative semiring with \((0,0)\) as the additive identity and \((1,0)\) as the multiplicative identity.

To create “negative” elements, we look at Quotient spaces. Define the equivalence relation “\(\sim\)” on \(S^2\) by

**Definition 7.4.** \((r,s) \sim (r_1,s_1) \iff r+s_1=s+r_1\)

**Lemma 7.5.** “\(\sim\)” is an equivalence relation.

**Proof.** (a) (Reflexive) \((r,s) \sim (r,s)\) is clear is + is commutative.
(b) (Symmetric) \( (r,s) \sim (r_1,s_1) \implies r + s = s + r_1 \implies r_1 + s = s_1 + r \implies (r_1,s_1) \sim (r,s) \)

(c) (Transitive) Suppose \( (r,s) \sim (r_1,s_1) \), and \( (r_1,s_1) \sim (r_2,r_2) \). So \( r + s = s_1 + r_1 \), and \( r_1 + r_2 = s_1 + r_2 \). Add these two equations together to get \( r + s + r_1 + r_2 = s + r_1 + s_1 + r_2 \). Since \( S \) is cancellative, we get \( r + r_2 = s + r_2 \). Therefore, \( (r,s) \sim (r_2,r_2) \).

Consider the equivalence classes: \( \overline{(r,s)} = \{(r_1,s_1) \mid (r_1,s_1) \sim (r,s)\} \) and let \( \overline{\frac{s}{s}} \equiv \{(r,s)\} \).

**Definition 7.6**. Let \( \overline{(r,s)}, \overline{(r_1,s_1)} \in \overline{\frac{s}{s}} \), then

(a) \( \overline{(r,s)} \equiv \overline{(r_1,s_1)} \equiv \overline{(r + r_1, s + s_1)} \)

(b) \( \overline{(r,s)} \equiv \overline{(r_1,s_1)} \equiv \overline{rr_1 + ss_1, rs_1 + s_1r_1} \)

We need to show that these operations are well-defined.

(a) (\( 
\equiv \)) Let \( (r,s) \sim (r_1,s_1) \) and \( (p,q) \sim (p_1,q_1) \). We need to show that

\[
\overline{(r,s)} \equiv \overline{(p,q)} = \overline{(r_1,s_1)} \equiv \overline{(p_1,q_1)}
\]

\[
(r + p, s + q) = (r_1 + p_1, s_1 + q_1)
\]

\[
(r + p, s + q) \sim (r_1 + p_1, s_1 + q_1)
\]

To this end, we have:

\[r + s = s + r_1\] \hspace{1cm} (69)

\[p + q = q + p_1\] \hspace{1cm} (70)

Add equations (69) and (70) together. Since \( S \) is associative, and commutative, we get:

\[
(r + p) + (s_1 + q_1) = (s + q) + (r_1 + p_1)
\]

Therefore \( (r + p, s + q) \sim (r_1 + p_1, s_1 + q_1) \), and Equation (68) is verified, and \( \equiv \) is well-defined.

(b) (\( \equiv \)) Let \( (r,s) \sim (r_1,s_1) \) and \( (p,q) \sim (p_1,q_1) \). We need to show that

\[
\overline{(r,s)} \equiv \overline{(p,q)} = \overline{(r_1,s_1)} \equiv \overline{(p_1,q_1)}
\]

\[
(rp + pq, rq + sp) = (r_1p_1 + s_1q_1, r_1q_1 + s_1p_1)
\]

\[
(rp + pq, rq + sp) \sim (r_1p_1 + s_1q_1, r_1q_1 + s_1p_1)
\]

55
To this end, we have:

\[ r + s_1 = s + r_1 \quad (75) \]
\[ p + q_1 = q + p_1 \quad (76) \]

We multiply:

(a) Equation (75) by “p”

(b) Equation (76) by “q”

(c) Equation (75) by “r_1”

(d) Equation (76) by “s_1”

To get, respectively:

\[ pr + ps_1 = ps + pr_1 \quad (77) \]
\[ qr + qs_1 = qs + qr_1 \quad (78) \]
\[ pr_1 + q_1 r_1 = qr_1 + p_1 r_1 \quad (79) \]
\[ ps_1 + q_1 s_1 = qs_1 + p_1 s_1 \quad (80) \]

Add the equations by setting:

\[ \text{LHS}_{(77)} + \text{RHS}_{(78)} + \text{LHS}_{(79)} + \text{RHS}_{(80)} = \text{RHS}_{(77)} + \text{LHS}_{(78)} + \text{RHS}_{(79)} + \text{LHS}_{(80)} \]

Using the commutative and associative properties of S, we get:

\[ (rp + sq) + (r_1 q_1 + s_1 p_1) + (ps_1 + qr_1 + pr_1 + qs_1) \]
\[ = (ps + qr) + (r_1 p_1 + s_1 q_1) + (pr_1 + q_1 s_1 + qr_1 + ps_1) \quad (81) \]

and using the cancellative property of S, we get:

\[ (rp + sq) + (r_1 q_1 + s_1 p_1) = (ps + qr) + (r_1 p_1 + s_1 q_1) \quad (82) \]

Therefore, \((rp + sq, rq + sp) \sim (r_1 p_1 + s_1 q_1, r_1 q_1 + s_1 p_1)\), and Equation (74) is verified. We have shown that \(\square\) is well-defined.

Let \(R^D \equiv (\frac{R^2}{0}, \boxplus, \boxtimes)\)

In \(R^D \overline{(a, a)} = (0, 0)\) is the additive identity, as:

\[ (a, a) \oplus (r, s) = (a + r, a + s) \sim (r, s) \quad (83) \]
\[ \implies \overline{(a, a) \oplus (r, s)} = \overline{(a + r, a + s)} = \overline{(r, s)} \quad (84) \]

And \(\overline{(a, a)}\) is absorbing under \(\boxtimes\), as:

\[ (a, a) \otimes (r, s) = (ar + as, as + ar) \sim (0, 0) \quad (85) \]
\[ \implies \overline{(a, a) \otimes (r, s)} = \overline{(0, 0)} \quad (86) \]
Let \( S_2 = \{ (a, 0) \in S^2 \mid a \in S \} \).

We now consider the mapping: \( \varphi : S \to R^D \), defined by \( \varphi(a) = (a, 0) \).

\[
\varphi(a + b) = (a + b, 0) = (a, 0) \boxplus (b, 0) = \varphi(a) \boxplus \varphi(b)
\]

(87)

\[
\varphi(ab) = (ab, 0) = (a, 0) \boxdot (b, 0) = \varphi(a) \boxdot \varphi(b)
\]

(88)

Therefore \( \varphi \) is a homomorphism from \( S \) to \( R^D \).

\[
\varphi(a) = \varphi(b) \iff (a, 0) = (b, 0) \iff (a, 0) \sim (b, 0) \iff a + 0 \, b + 0 \iff a = b
\]

Hence, \( \varphi \) is one-to-one, and we have an isomorphism between \( S \) and \( S_2 \).

\[\square\]

With this embedding we can identify a cancellative semiring with its isomorphic image in its “ring of differences.” We can consider the semiring as a subsemiring of \( R^D \).

Figure 3 is a representation of these relationships. We use \( \varphi_1 \) as the isomorphism between \( S \) and \( S_2 \), and \( \varphi_2 \) as the epimorphism from \( S \) to \( S_2 \).

With the use of Propositions 7.1 and 7.2, we are able to conclude things about the semiring \( S_1 \), by considering the ring \( R^D \). In particular any identity in \( R^D \) which is wholly in \( S_2 \) can be carried over to \( S_1 \) by going, first, through the semiring \( S \). We will consider identities in rings which have an analogous identity in semirings. We refer to section 8.11 for these identities. First, we study the new algebra of multisets.
8 Multiset Algebra

In this section we consider the algebraic structure of the Multiset algebra, abbreviated as the Mset Algebra. A multiset, or mset, is a collection of elements in which repetition is allowed. An mset can be thought of a “set” in which multiplicities are allowed. For example, \(\{1,2,2\} = \{2,1,2\} \neq \{1,2\}\). The operations of intersection and union work similarly with multisets as they do with sets. If \(\alpha\) and \(\beta\) are two multisets then \(\alpha \cap \beta = \delta\), where \(\delta\) is the smallest mset which is contained in \(\alpha\) and \(\beta\).

The motivation that inspires us to consider multisets over \(\mathbb{S}\), or \(3^\mathbb{S}\), is that this allows much more information to be kept throughout the problem. As we see throughout the following sections there is much more available information accessible for our use. However, keeping these extra pieces of information results in some equations which are not solvable in the sense of being able to write down an explicit solution to the equation. All that is possible is a “consistency condition” that allows us to characterize the solution to the equation. In some cases we are able to give an algorithmic method to solve the equation. If \(\mathbb{S}\) is a semiring, then if the problem is translated back to the system \(\mathbb{S}\), then in many cases, a solution is available. Throughout this section, it may be realized that the field \(\mathbb{R}\) is an underlying structure which motivates the development of the subject of the mset algebra.

8.1 Notation and Definitions

We begin with a set \(\mathbb{S}\), along with two binary operations:

(a) \(\oplus\), which is associative and commutative, with additive identity \(\theta\).

(b) \(\odot\), which is associative and commutative, with multiplicative identity \(e\).

(c) \(\odot\) is distributive over \(\oplus\).

Consider the set \(3^\mathbb{S}\) derived from the basic set \(\mathbb{S}\) above. \(3^\mathbb{S}\) is the “power set” of all finite multisets with elements from \(\mathbb{S}\). We use \(3^\mathbb{S}\) for the power set instead of the more familiar \(2^\mathbb{S}\) to highlight the difference between sets and multisets.

**Definition 8.1.** With the new system \(3^\mathbb{S}\), we have the operations of:

1. \(\uplus\), called ‘fusion’, an ‘addition’

2. \(\otimes\), a ‘multiplication’

We use the name ‘fusion’ to signify that this operation is different from ‘union’ which is used with sets, and ‘concatenation’ which implies that order matters.

The symbol \(4^\mathbb{S}\) can be used as the power set of \(\mathbb{S}\) which allows infinite sets. The multisets in this thesis will be assumed finite, so there is no need for this power set.
**Definition 8.2.** We make the following definitions in the mset algebra:

Let \( \alpha = \{ a_1, a_2, \ldots, a_k \} \), and \( \beta = \{ b_1, b_2, \ldots, b_m \} \), with \( a_i, b_j \in \mathbb{S} \). Then

1. \( \{ a \} \uplus \{ b \} \equiv \{ a, b \} \), with \( a, b \in \mathbb{S} \).
2. \( \alpha \uplus \beta = \{ a_1, a_2, \ldots, a_k, b_1, b_2, \ldots, b_m \} \)
3. \( \{ a \} \boxtimes \{ b \} \equiv \{ a \odot b \} \) (product with \( \odot \) from the set \( \mathbb{S} \)) usually written \( a \beta \).
4. If \( \{ a \} \in 3^\mathbb{S} \), then \( \{ a \} \boxtimes \{ b_1, b_2, \ldots, b_n \} = \{ a \odot b_1, a \odot b_2, \ldots, a \odot b_n \} \).
5. \( \alpha \boxtimes \beta = \{ a_i \odot b_j \mid a_i \in \alpha, b_j \in \beta \} \).
6. \( \alpha \boxtimes \beta = \uplus \biguplus_{i,j} a_i \odot b_j \)
7. The elements of \( \mathbb{S} \) are the scalars of \( 3^\mathbb{S} \).
8. \( |\alpha| \equiv \) the number of elements in \( \alpha \).
9. \( |\alpha \boxtimes \beta| = |\alpha| \cdot |\beta| \)
10. If \( \alpha \in 3^\mathbb{S} \), then \( \alpha^n = \underbrace{\alpha \boxtimes \alpha \boxtimes \cdots \boxtimes \alpha}_{n \text{ times}} \).
11. If \( |\alpha| = k \), then \( |\alpha^n| = k^n \)

As a matter of illustration, a multiset can be thought of as a linear combination of the distinct elements of the multiset. For example, the multiset \( \{ a, a, a, b, b, c \} \) can be written as \( \{ 3a, 2b, c \} \). This allows a nice formulation of our 'fusion' operation. As an example, we could define \( \{ 2a, 3b, c \} \uplus \{ 4a, 2b, c \} = \{ 6a, 5b, 2c \} \). The elements of \( \mathbb{Z} \) are used to 'keep track' of the number of times an element appears in the multiset. The "mset intersection" can be formulated as "take each element appearing in both mssets and keep the smaller coefficient." The "mset union" can be formulated as "take each element appearing in both mssets and keep the largest coefficient."

In this thesis, we will not use this method of 'keeping track' of the elements, but will only list all the elements in the multiset explicitly; although the mset union and mset intersection can be calculated with these definitions in mind.

### 8.2 Properties

In this section we list the basic properties of the operations of the mset algebra.

**Proposition 8.3 (Properties of \( \uplus \) under \( 3^\mathbb{S} \)).** If \( \alpha, \beta, \gamma \in 3^\mathbb{S} \), then

1. \( 3^\mathbb{S} \) is closed under \( \uplus \)
(2) $\uplus$ is associative. $\alpha \uplus (\beta \uplus \gamma) = (\alpha \uplus \beta) \uplus \gamma$

String the sets together, and rearrange in the appropriate order. Order does not matter in the multisets.

(3) $\uplus$ is commutative. $\alpha \uplus \beta = \beta \uplus \alpha$

There is no order in the sets, just rearrange the sets.

(4) $\emptyset$, the empty set, is the additive identity.

$\emptyset \uplus \alpha = \alpha$.

(5) $|\alpha \uplus \beta| = |\alpha| + |\beta|$.

(6) $3^5$ is cancellative.

If $\alpha$, $\beta$, and $\gamma$ are multisets, and $\alpha \uplus \beta = \alpha \uplus \gamma$, then $\beta = \gamma$.

(7) $\uplus$ is NOT idempotent.

$\alpha \uplus \alpha \neq \alpha$

$\{ a \} \uplus \{ a \} = \{ a, a \}$.

(8) There are NO additive inverses in $3^5$.

If $\alpha \in 3^5$ and $\alpha \neq \emptyset$, then there is no element, $\beta$ of $3^5$ such that $\alpha \uplus \beta = \emptyset$.

(9) $3^5$ is zerounfree.

If $\alpha \uplus \beta = \emptyset$ then $\alpha = \beta = \emptyset$.

**Example 8.4.** $\{1,2,2\} \uplus \{1,2,3\} = \{1,1,2,2,2,3\}$

**Proposition 8.5 (Properties of $\boxdot$ under $3^5$).** If $\alpha, \beta, \gamma \in 3^5$, then

(1) $3^5$ is closed under $\boxdot$

(2) $\boxdot$ is associative.

$$\alpha \boxdot (\beta \boxdot \gamma) = (\alpha \boxdot \beta) \boxdot \gamma = \bigcup_{i,j,k} \alpha_i \cap \beta_j \cap \gamma_k$$

(3) $\boxdot$ is commutative.

$$\alpha \boxdot \beta = \beta \boxdot \alpha$$

(4) $\boxdot$ is distributive over $\uplus$.

(5) $|\alpha \boxdot \beta| = |\alpha| \cdot |\beta|$.
(6) \{1\}, the multiplicative identity of \(\mathbb{S}\), is the multiplicative identity.
\[ \{1\} \boxtimes \{a\} = \{a\}. \]

(7) \(\emptyset\) is absorbing under \(\boxtimes\).
\[ \emptyset \boxtimes \{a\} = \emptyset. \]

(8) If \(\alpha = \beta\), then \(\alpha \boxtimes \gamma = \beta \boxtimes \gamma\).

(9) If \(\alpha \boxtimes \gamma = \beta \boxtimes \gamma\), then it does not follow that \(\alpha = \beta\). Example: \(\{1\} \boxtimes \{2, -2\} = \{-1\} \boxtimes \{2, -2\}\).

(10) \(\{0\} \boxtimes \alpha = \{0, \ldots, 0\}_{1 \times k}\), where \(k = |\alpha|\).

(11) \(\mathbb{S} \subset 3^\mathbb{S}\). We can associate the elements of \(\mathbb{S}\) with the singletons, or scalars, of \(3^\mathbb{S}\).

(12) Multiplicative inverses in \(3^\mathbb{S}\):
If \(a \in \mathbb{S}\), and \(a\) is invertible in \(\mathbb{S}\), then \(\{a\} \boxtimes \{a^{-1}\} = \{1\}\).

**Example 8.6.** \(\{1, 2, 3\} \boxtimes \{4, 5\} = \{4, 5, 8, 10, 12, 15\}\).

**Proposition 8.7.** If \(\alpha = (\alpha^+, \theta_a, \alpha^-)\), and \(\beta = (\beta^+, \theta_\beta, \beta^-)\), then we can more rigorously define the size of the product of these two multisets. Suppose \(\alpha \boxtimes \beta = \gamma\), and let

\[
\begin{align*}
|\alpha| &= k \\
|\beta| &= \ell \\
|\gamma| &= u \\
|\alpha^+| &= m \\
|\beta^+| &= q \\
|\gamma^+| &= v \\
|\alpha^-| &= n \\
|\beta^-| &= r \\
|\gamma^-| &= w \\
|\theta_a| &= p \\
|\theta_\beta| &= t \\
|\theta_\gamma| &= y
\end{align*}
\]

Then \(|\alpha \boxtimes \beta| = k \cdot \ell = (m + n + p) \cdot (q + r + t)\)

In what follows we will consider a multiset as consisting of two parts: a multiset with all positive elements, and a multiset with all negative elements. We may write this as \(\alpha = \{\alpha^+, \alpha^-\}\).

The element \(\theta \in \mathbb{S}\) warrants special attention. At the beginning of this development, a multiset was split into 3 parts: \(\alpha = \{\alpha^+, \theta_a, \alpha^-\}\), where \(\theta_a\) is a multiset consisting of all the zeros of \(\alpha\) (see Proposition 8.7). As the work progressed it was seen that the \(\theta_a\)-multiset does not affect the outcome. It only adds a consistency condition which must be satisfied. As we see from Equation (91), in using \(\varphi_a\) \((\alpha)\), the zeros of \(\mathbb{S}\) do not affect the sum, since \(\theta\) is the additive identity of \(\mathbb{S}\).

With the properties illustrated above, we have the following lemma.

**Lemma 8.8.** If \(\mathbb{S}\) is a semiring then \(3^\mathbb{S}\) is a cancellative zero-sumfree semiring with no zero divisors.
It should be noticed, here, that $3^S$ is a semiring with a cancellation property (where cancellation is defined as dropping elements of a multiset from each side of an equation), whereas the set $S = \mathcal{M}^*$, as a path algebra, is a semiring with idempotency. In this respect we have traded the idempotency property for a cancellation property. As we compare these two semirings, we also note that the addition of $S$ ($\oplus$) does not play a role in $3^S$; only the multiplication of $S$ is used in the development of the mset algebra.

### 8.3 Mappings

In this section we define mappings from $S$ to $3^S$, and from $3^S$ to $S$.

#### Definition 8.9
Define $\varphi : S \rightarrow 3^S$ by:

$$
\varphi_s(a) = \begin{cases} 
\{a\} & \text{if } a \neq \theta \\
\varnothing & \text{if } a = \theta
\end{cases}
$$

#### Definition 8.10
Define $\varphi^{-1} : 3^S \rightarrow S$ by:

$$
\varphi^{-1}_s(\alpha) = \bigoplus_i^n a_i \\
\theta & \text{if } \alpha = \varnothing
$$

#### Proposition 8.11
If $a \in S$, then $\varphi^{-1}_s(\varphi_s(a)) = a$

#### Note 8.12
If $\alpha \in 3^S$, then $\varphi_s(\varphi^{-1}_s(\alpha)) \neq \alpha$, unless $\alpha$ consists of only one element.

In our development of the mset algebra, the addition operation of $S$ is not used. Definition 8.10 shows how the addition operation of $S$ is connected to the mset algebra. See Section 8.16 for more the mapping of Definition 8.10.

#### Definition 8.13
If $A \in S_{n \times n}$, then

$$
[\varphi_s(A)]_{ij} = \begin{cases} 
\{a_{ij}\} & \text{if } a_{ij} \neq \theta \\
\varnothing & \text{if } a_{ij} = \theta
\end{cases}
$$

### 8.4 Matrices over $3^S$

Suppose $A, B \in 3^S_{n \times n}$, and $\alpha \in 3^S$, then we define:

1. $(A \uplus B)_{ij} \equiv a_{ij} \uplus b_{ij}$,
2. \((A \boxtimes B)_{ij} \equiv \bigcup_k \{a_{ik} \boxtimes b_{kj}\} = \{a_{i1} \circ b_{1j}, a_{i2} \circ b_{2j}, \ldots, a_{in} \circ b_{nj}\}\).

3. \((\alpha \boxtimes A)_{ij} \equiv \alpha \boxtimes a_{ij}\)

**Example 8.14.** If \(A \in 3^S_{n \times n}\) then

1. \(a_{ij} = \text{mset}\)
2. \(A^{1}_{ij} = \{a_{i1} \boxtimes a_{1j}, a_{i2} \boxtimes a_{2j}, \ldots, a_{in} \boxtimes a_{nj}\}\).
3. \(A^{2}_{ij} = \bigcup_{k_1, k_2} \{a_{ik_1} \boxtimes a_{k_1 k_2} \boxtimes a_{k_2 j}\}\).
4. \(A^{m}_{ij} = \bigcup_{k_1, k_2, \ldots, k_{m-1}} \bigcup_{k_m} \{a_{ik_1} \boxtimes a_{k_1 k_2} \boxtimes \cdots \boxtimes a_{k_{m-1} j}\}\).

**Proposition 8.15.** \(3^S_{n \times n}\) is a cancellative zerosumfree semiring with multiplicative identity.

**Proposition 8.16.**

1. \(\emptyset_n = \begin{bmatrix} \emptyset & \cdots & \emptyset \\ \vdots & \ddots & \vdots \\ \emptyset & \cdots & \emptyset \end{bmatrix}\) is the additive identity.

2. \(I_n = \begin{bmatrix} \{1\} & \cdots & \emptyset \\ \vdots & \ddots & \vdots \\ \emptyset & \cdots & \{1\} \end{bmatrix}\) is the multiplicative identity.

**Proposition 8.17.** If \(A \in 3^S_{n \times n}\), then:

1. \(\emptyset_n \uplus A = A\)
2. \(\emptyset_n \boxtimes A = A \boxtimes \emptyset_n = \emptyset_n\)
3. \(I_n \boxtimes A = A \boxtimes I_n = A\)
8.5 Partial Ordering and Lattice Structure

Here, we give a brief result for msets.

**Definition 8.18.** We use the notation $\alpha \subseteq \beta$ to mean that each element (including multiplicities) of $\alpha$ is also in $\beta$.

**Proposition 8.19.** Mset-inclusion induces a partial order on $3^R$.

*Proof.* Suppose $\alpha, \beta, \gamma \in 3^R$.

1. $\alpha \subseteq \alpha$.
2. If $\alpha \subseteq \beta$ and $\beta \subseteq \alpha$, then $\alpha = \beta$.
3. If $\alpha \subseteq \beta$ and $\beta \subseteq \gamma$, then $\alpha \subseteq \gamma$. \hfill $\square$

**Definition 8.20.** We say that $\alpha \leq \beta$ if and only if $\alpha \subseteq \beta$.

We use the usual meaning for vectors, i.e. $x \leq y$ means elementwise. Likewise $x \geq \emptyset$ means $x_i \geq \emptyset$, and at least one element of $x$ is greater than $\emptyset$.

The partial ordering on $3^R$ creates a lattice structure on $3^R$, where

1. $\alpha \wedge \beta = \alpha \cap \beta$, where ‘$\cap$’ represents mset intersection.
2. $\alpha \vee \beta = \alpha \cup \beta$, where ‘$\cup$’ represents the mset union.

8.6 Equations in $3^S$

In this section we investigate equations with coefficients in $3^S$. After developing the algebra of $3^S$, we are interested in the solvability of certain types of equations. We assume throughout this section that $S$ has a total order and that the nonzero elements of $S$ have multiplicative inverses. It is noted that this is true for $\mathbb{R}$ which is a field, and for the algebras $\mathcal{M}^+$ and $\mathcal{M}^*$ which have been used earlier in this thesis.

**Lemma 8.21.** Suppose $S$ is a semiring in which the nonzero elements have multiplicative inverses, and suppose that $S$ is totally ordered. Let $P$ be the set of “positive” elements of $S$, $P = \{a \mid a > \theta\}$. If $\alpha, \beta, \gamma \in P$ and $\alpha \boxplus \beta = \alpha \boxplus \gamma$, then $\beta = \gamma$.

*Proof.* Write the elements of $\alpha, \beta, \gamma$ is increasing order. Then $a_1b_1 = a_1c_1$, since each product is the minimal element of the multiset. Since $a_1 > \theta$, and $a_1^{-1}$ exists, then multiply both sides by $a_1^{-1}$, and conclude that $b_1 = c_1$. Form $\beta' = \beta \setminus \{b_1 \boxplus \alpha\}$, and $\gamma' = \gamma \setminus \{c_1 \boxplus \alpha\}$, and repeat. \hfill $\square$
Example 8.22. Lemma 8.21 is not valid if “negative” numbers are allowed in \( \alpha \). Consider \( S = \mathbb{R} \) with the usual multiplication. \( \{1\} \{1, -1\} = \{-1\} \{1, -1\} \), but \( \{1\} \neq \{-1\} \).

Lemma 8.23. If \( \alpha, \beta, \gamma \in \mathbb{R} \), and \( \alpha < 0, \beta > 0, \gamma > 0 \), and \( \alpha \boxtimes \beta = \alpha \boxtimes \gamma \), then \( \beta = \gamma \)

Proof. The proof is similar to the proof of Lemma 8.21.

Note 8.24. We use \( \mathbb{R} \), mssets over the real numbers in the rest of this section.

For mssets, \( \gamma > 0 \) means that every element of the msset \( \alpha \) is positive.

Proposition 8.25. Solve the equation: \( \alpha \boxtimes x = \emptyset \).

If \( \alpha \neq \emptyset \), then \( x = \emptyset \) is the unique solution.

The above proposition may be restated as:
\[ \alpha \boxtimes x = \emptyset \implies \alpha = \emptyset \text{, or } x = \emptyset \]

Lemma 8.26. If \( \alpha > 0, \beta > 0, \) and \( \alpha^2 = \beta^2 \), then \( \alpha = \beta \).

Proof. Suppose \( \alpha > 0 \) and \( \beta > 0 \). Assume \( \alpha \), and \( \beta \) are in ascending order. \( a_1 \leq a_2 \leq \cdots \leq a_n \) and \( b_1 \leq b_2 \leq \cdots \leq b_n \). Then \( \alpha^2 = \beta^2 \). So \( a_1 = b_1 \). Form \( \alpha' = \alpha \setminus (a_1 \boxtimes \alpha) \), and \( \beta' = \beta \setminus (a_1 \boxtimes \alpha) \). Continue to get \( \alpha = \beta \).

Lemma 8.27. If \( \alpha u \uplus \beta v = \beta u \uplus \alpha v \), and \( \alpha, \beta, u, v > 0 \), then \( \alpha = \beta \), or \( u = v \).

Proof. Write \( u = u_1 \uplus u_2 \), and \( v = v_1 \uplus v_2 \) with \( u_1 = u \cap v = v_1 \).

\[
\alpha u_1 \uplus \alpha u_2 \uplus \beta v_1 \uplus \beta v_2 = \beta u_1 \uplus \beta u_2 \uplus \alpha v_1 \uplus \alpha v_2 \\
\implies \alpha u_2 \uplus \beta v_2 = \beta u_2 \uplus \alpha v_2
\]

In Equation (94), \( u_2 \), and \( v_2 \), have no elements in common. So we will assume that in Lemma 8.27, that this is also the case. So suppose we have
\[ \alpha u \uplus \beta v = \beta u \uplus \alpha v \] (95)

with \( u \), and \( v \) having no common elements. Assume \( \alpha, \beta, u, \) and \( v \) are written with their elements in ascending order. Consider the minimal element on each side of Equation (95):
\[ \min\{\alpha_1 u_1, \beta_1 v_1\} = \min\{\beta_1 u_1, \alpha_1 v_1\} \] (96)

There are four cases to be investigated:

1. \( \alpha_1 u_1 = \beta_1 u_1 \implies \alpha_1 = \beta_1 \)
\[(2) \quad \alpha_1 u_1 = \alpha_1 v_1 \implies u_1 = v_1 \]
\[(3) \quad \beta_1 v_1 = \beta_1 u_1 \implies u_1 = v_1 \]
\[(4) \quad \beta_1 v_1 = \alpha_1 v_1 \implies \alpha_1 = \beta_1 \]

We can now reduce the size of the appropriate mset, and continue. \(\Box\)

The constraints of Lemma 8.27 can be relaxed to the following lemma, whose proof is similar to the proof of Lemma 8.27

**Lemma 8.28.** If \(\alpha u \cup \beta v = \beta u \cup \alpha v\), and \(\alpha, \beta > 0\), then \(\alpha = \beta\), or \(u = v\).

The proof of the following is also similar to the proof of Lemma 8.27.

**Lemma 8.29.** If \(\alpha \boxplus x = \beta \boxplus x\), and \(x > 0\), then \(\alpha = \beta\)

**Example 8.30.** Solve the equation:

\[\alpha \boxplus x = \beta\]  \hspace{1cm} (97)

The consistency condition for this equation is: \(|\alpha| \cdot |x| = |\beta|\).

This equation is separated into three cases

1. \(\alpha > 0\) and \(\beta > 0\).
   
   Then \(x > 0\), and this is just Lemma 8.21.

2. \(\beta > 0\). Then there are two cases, as \(\alpha\) and \(x\) cannot contain both positive and negative elements.

   (a) \(\alpha > 0\), and \(x > 0\).
   
   This is just the previous case.

   (b) \(\alpha < 0\), and \(x < 0\).
   
   The proof of this is similar to the previous case, or to that of Lemma 8.21.

3. (General Case) \((\alpha^+, \alpha^-)(x^+, x^-) = (\beta^+, \beta^-)\)
   
   This leads to the two equations:

   \[\alpha^+ x^+ \cup \alpha^- x^- = \beta^+\] \hspace{1cm} (98)

   \[\alpha^- x^+ \cup \alpha^+ x^- = \beta^-\] \hspace{1cm} (99)

Here, we let \(a=\alpha^+, b=-\alpha^-, x=x^+, y=-x^-, c=\beta^+,\) and \(d=-\beta^-\) to yield:
\[
\begin{bmatrix}
a & b \\
b & a
\end{bmatrix}
\begin{bmatrix}
x \\
y
\end{bmatrix}
=
\begin{bmatrix}
c \\
d
\end{bmatrix}
\] (100)

where all entries are positive.

This can be written as:

\[
ax \oplus by = c \tag{101}
\]

\[
bx \oplus ay = d \tag{102}
\]

If we multiply equation (101) by 'a' and equation (102) by 'b', combine the two equations and cancel the common term of 'aby', then we get:

\[
a^2x \oplus bd = b^2x \oplus ac \tag{103}
\]

Likewise, we multiply equation (101) by 'b', and equation (102) by 'a', combine the two equations and cancel the common term of 'aby', and get:

\[
a^2y \oplus bc = b^2y \oplus ad \tag{104}
\]

Equations (103), and (104) are equivalent to the solutions associated with Cramer’s Rule. Each of these equations is an equation with only one variable. We are not able to solve these systems for 'x' or 'y'.

An “algebraic” solution for \(x = \{x^+, x^-\}\) is not possible in this case as the problem depends greatly on \(\beta\).

\[
\]

It is possible to use an algorithm to solve for \(x = \{x^+, x^-\}\), but the available algorithm grows exponentially.

**Algorithm 8.31.** To solve \(ax = \beta\)

1. Set \(n = \left| \frac{b}{a} \right| \) If \(\alpha \nmid \beta\) then no solution exists.

2. Calculate:

   \[
   \begin{align*}
   (2a) \quad \hat{x} &= x^+_{\text{max}} = \frac{\beta^-}{\alpha_{\text{min}}} \\
   (2b) \quad x' &= x^-_{\text{min}} = \frac{\beta^-}{\alpha_{\text{max}}}
   \end{align*}
   \]

3. Calculate:

   \[
   (3a) \quad \alpha \hat{x}
   \]
(3b) $\alpha x'$

(4) For each of parts (3a) and (3b) above, if all elements of the set are elements of $\beta$, then cancel these elements from $\beta$. Replace $\beta$ by $\beta \setminus (\alpha \hat{x})$ or $\beta \setminus (\alpha x')$

(5) Repeat at step (2) until $\beta = \emptyset$.

If, at any step, a contradiction occurs, then back out to the next branch. If all branches occur with no solution, then no solution exists.

The following is another description of the algorithm. Consider $(\alpha^-, \alpha^+)(x^-, x^+) = (\beta^-, \beta^+)$. Then $\beta^-$ is obtained from either (1) $\alpha^- x_n^+$ or (2) $\alpha_n^+ x_1^-$. From these two equations, we find either (1) $x_n^+ = \frac{\beta^-}{\alpha^-}$, or (2) $x_1^- = \frac{\beta^-}{\alpha_n^+}$. We pick one of these two choices, multiply by $\alpha$, and cancel the appropriate terms from $\beta$, and continue to find the next element of “$x$”. If all the terms of $\alpha * x_n^+$ (or the other) are not present, then we try the other choice. If it does not work then there is not solution. This algorithm will continue until we have solved for “$x$”, or until we have tried all $2^n$ choices for the elements of “$x$”.

**Example 8.32.** Use Algorithm 8.31 to solve: $\{2, 3\} x = \{-9, -6, 4, 6, 9\}$.

$|x| = 3$, $\implies x = \{x_1, x_2, x_3\}$

(1) $\{2, 3\} \{x_1, x_2, x_3\} = \{-9, -6, 4, 6, 9\}$.

(a) $\hat{x} = \frac{-9}{2} = -4.5$

(i) $\alpha \hat{x} \notin \beta$

(ii) no good.

(b) $\alpha x' = \frac{-3}{2} = -1.5$

(i) $\alpha x' = \{-9, -6\}$

(ii) $\beta$ replaced by $\beta \setminus (\alpha x')$

(2) $\{2, 3\} \{x_2, x_3\} = \{4, 6, 9\}$.

(a) $\hat{x} = \frac{2}{3} = 2$

(i) $\alpha \hat{x} = \{4, 6\}$

(ii) $\beta$ replaced by $\beta \setminus (\alpha \hat{x})$

(b) $\alpha x' = \frac{3}{2}$

(i) $\alpha x' \notin \beta$

(ii) no good.

(3) $\{2, 3\} \{x_3\} = \{6, 9\}$. 

68
(a) \( \tilde{x} = \frac{9}{3} = 3 \)

(i) \( \alpha \tilde{x} = \{6, 9\} \)

(ii) \( \beta \) replaced by \( \beta \setminus (a \tilde{x}) \)

(iii) \( \beta = \emptyset \).

(iv) Complete.

(b) \( x' = \frac{6}{3} = 2 \)

(i) \( \alpha x' \notin \beta \)

(ii) no good.

For this example, we see that \( x = \{-3, 2, 3\} \). □

We can also use Algorithm 8.39 to solve Equations (103) and (104) to arrive at a solution to Equation (97).

**Example 8.33.** Solve the equation: \( \alpha \boxdot x = \beta \boxdot x \).

The consistency condition for this equation is: \( |\alpha| \cdot |x| = |\beta| \cdot |x| \), or \( |\alpha| = |\beta| \).

We consider three different cases to analyze this equation.

1. \( \alpha > 0, \beta > 0, x > 0 \).
   Assume \( \alpha, \beta, \) and \( x \) are written in increasing order. Then \( \alpha_1 \boxdot x_1 = \beta_1 x_1 \). Multiply by \( x_1^{-1} \) to get \( \alpha_1 = \beta \). Form \( \beta' = \beta \setminus \beta_1, \alpha' = \alpha \setminus \alpha_1 \). The new equation is \( \alpha' \boxdot x = \beta' \). Continue to find \( \alpha_2 = \beta_2, \alpha_3 = \beta_3, \ldots \). Therefore, we get that \( \alpha = \beta \).

2. \( \beta > 0 \).
   Write \( \{\alpha^+, \alpha^-\} \{x^+, x^-\} = \beta \{x^+, x^-\} \).
   
   \[
   \begin{align*}
   \alpha^+ x^+ \cup \alpha^- x^- &= \beta x^+ \quad \text{(105)} \\
   \alpha^- x^+ \cup \alpha^+ x^- &= \beta x^+ \quad \text{(106)}
   \end{align*}
   
   Multiply Equation (105) by \( x^- \), and Equation (106) by \( x^+ \). Combine the equations and cancel \( \alpha^+ x^+ x^- \) to get:

   \[
   \alpha^- (x^-)^2 = \alpha^- (x^+)^2 \quad \text{(107)}
   \]

   If we let \( a = x^+, b = x^-, d = \alpha^- \), and \( d = -\alpha^- \), then the equation becomes:

   \[
   d(b)^2 = d(a)^2 \quad \text{(108)}
   \]
By Lemma 8.23,

\[(b)^2 = (a)^2\]  \hspace{1cm} (109)

So by Lemma 8.26, \(b = a\).

So, \(x^+ = -x^-\). This is the first condition to solve the equation.

Equation (105) becomes

\[
\alpha^+ x^+ \uplus (-\alpha^-)(-x^-) = \beta x^+
\]

\[
\implies \alpha^+ x^+ \uplus (-\alpha^-) x^+ = \beta x^+
\]

\[
\implies (\alpha^+ \uplus (-\alpha^-)) x^+ = \beta x^+
\]

\[
\implies \alpha^+ \uplus (-\alpha^-) = \beta
\]

So, we have that \(x^+ = -x^-\), and \(\beta = \alpha^+ \uplus \alpha^-\).

(3) (General case).

\[
\{\alpha^+, \alpha^-\}\{x^+, x^-\} = \{\beta^+, \beta^-\}\{x^+, x^-\}
\]

(111)

The two equations are:

\[
\alpha^+ x^+ \uplus \alpha^- x^- = \beta^+ x^+ \uplus \beta^- x^-
\]

(112)

\[
\alpha^+ x^- \uplus \alpha^- x^+ = \beta^+ x^- \uplus \beta^- x^+
\]

(113)

If we let \(a = \alpha^+, b = -\alpha^-, c = \beta^+, d = -\beta^-, x = x^+, y = -x^-,\) then Equation (112) can be written as:

\[
\begin{bmatrix}
    a & b \\
    b & a
\end{bmatrix}
\begin{bmatrix}
    x \\
    y
\end{bmatrix}
=
\begin{bmatrix}
    c & d \\
    d & c
\end{bmatrix}
\begin{bmatrix}
    x \\
    y
\end{bmatrix}
\]

(114)

This system can be written as:

\[
a x \uplus b y = c x \uplus d y
\]

(115)

\[
b x \uplus a y = d x \uplus c y
\]

(116)

Multiply Equation (115) by 'a', and Equation (116) by 'b' to get

\[
a^2 x \uplus aby = ac x \uplus ad y
\]

(117)

\[
b^2 x \uplus aby = bd x \uplus bc y
\]

(118)

We add these equations together and cancel the term of 'aby' to get
\[ a^2 x \cup bd x \cup bcy = b^2 x \cup acx \cup ady \]  
\( \text{(119)} \)

And, we can also multiply Equation (115) by 'c', and Equation (116) by 'd', add together and cancel a common term of 'dry' to get:

\[ acx \cup d^2 x \cup bcy = c^2 x \cup bd x \cup ady \]  
\( \text{(120)} \)

We then add Equations (119) and (120) and cancel the common terms of 'ady' and 'bcy' to get the equation:

\[ (a^2 \cup bd \cup bd \cup c^2) x = (b^2 \cup ac \cup ac \cup d^2) x \]  
\( \text{(121)} \)

since \( x > 0 \). Then by Lemma 8.29,

\[ a^2 \cup bd \cup bd \cup c^2 = b^2 \cup ac \cup ac \cup d^2 \]  
\( \text{(122)} \)

This is the same equation one would get if the variable 'x' was eliminated from Equations (115) and (116), using the fact the \( y > 0 \).

Replacing the variables by the respective elements, we get:

\[ (\alpha^+)^2 \cup (\alpha^-)(\beta^-) \cup (\alpha^-)(\beta^-) \cup (\beta^+)^2 \]
\[ = (\alpha^-)^2 \cup \alpha^+ \beta^- \cup \alpha^+ \beta^- \cup (-\beta^-)^2 \]  
\( \text{(123)} \)

Equation (123) is a consistency condition; but it is not the consistency condition that we seek, since it does not allow us to proceed further.

So, we return to Equations (115) and (116): Multiply Equation (115) by 'y', multiply Equation (116) by 'x', combine the two equations, and cancel the common terms 'axy' and 'cxy' to get the equation:

\[ dx^2 \cup by^2 = bx^2 \cup dy^2 \]  
\( \text{(124)} \)

We can also multiply Equation (115) by 'x', multiply Equation (116) by 'y', combine the two equations, and cancel the common terms 'bxy' and 'dxy' to get the equation:

\[ ax^3 \cup cy^2 = cx^2 \cup ay^2 \]  
\( \text{(125)} \)
By applying Lemma 8.27 to Equations (124) and (125) we get conditions for the solution to the Equations (115) and (116): either \( x^+ = -x^- \), or \( \alpha^+ = \beta^+ \) and \( \alpha^- = \beta^- \).

So we have either:

(a) \( x^+ = -x^- \). In this case we go back to to equation (112) and get:

\[
\alpha^+ x^+ \uplus (-\alpha^-)(-x^-) = \beta^+ x^+ \uplus (-\beta^-)(-x^-)
\]

\[
\implies \alpha^+ x^+ \uplus (-\alpha^-)x^+ = \beta^+ x^+ \uplus (-\beta^-)x^+ \tag{126}
\]

This can be stated as: \( |\alpha| = |\beta| \), and the msets composed of the absolute values of the elements of \( \alpha \) and \( \beta \) are equal msets.

(b) \( \alpha = \beta \). Then \( x \) can be any mset.

\[\blacksquare\]

**Example 8.34.** Suppose that \( ax \subseteq \beta x \). Suppose, further, that \( \alpha, \beta, x > 0 \).

The following example shows that there does not need to be any relation between \( \alpha \) and \( \beta \). In particular \( \alpha \nsubseteq \beta \)!

This is a catastrophic example for it spoils many possible results involving eigenvalue equation proofs in the mset algebra.

\[
\{2, 5\} \boxtimes \{3, 4, 7\} \subseteq \left\{ \frac{8}{7}, \frac{3}{2}, \frac{15}{7}, \frac{14}{3}, \frac{20}{3}, \frac{35}{4} \right\} \boxtimes \{3, 4, 7\} \tag{127}
\]

The previous example proves the following important lemma.

**Lemma 8.35.**

\[
ax \subseteq \beta x \not\iff \alpha \subseteq \beta
\]

Although the following constraints are more strict than necessary, we have a more general case of Example 8.34.

**Example 8.36.** If \( a, b, c, p, q > 0 \) and \( a, b, c, p, q \) are all pairwise relatively prime then

\[
\{p, q\} \boxtimes \{a, b, c\} \subseteq \left\{ \frac{pb}{a}, \frac{qb}{a}, \frac{pc}{b}, \frac{qc}{b}, \frac{pa}{c}, \frac{qa}{c} \right\} \boxtimes \{a, b, c\} \tag{129}
\]

\[\blacksquare\]
Example 8.37. The general linear equation over msets is

$$\alpha \boxplus x \uplus \beta = \gamma \boxplus x \uplus \delta.$$  \hspace{1cm} (130)

This equation is too general for a full investigation of its general solutions. The consistency condition for this equation is \(|\alpha| \cdot |x| + |\beta| = |\gamma| \cdot |x| + |\delta|\). This is equivalent to the condition that

$$|x| = \frac{|\beta| - |\delta|}{|\alpha| - |\gamma|}.$$  This condition is not sufficient to determine whether a solution exists to the equation.

Example 8.38. Let us consider the equation, with \(\alpha, \beta, \gamma, \delta > 0\).

$$\alpha \boxplus x \uplus \beta = \gamma \boxplus x \uplus \delta.$$  \hspace{1cm} (131)

with \(\alpha, \beta, \gamma, \delta > 0\).

We assume that all elements are positive, and that they are in increasing order. The assumption that \(\alpha, \beta, \gamma, \delta > 0\) is not too restrictive in the sense that Equation (131) is the equation which results from using Cramer’s Rule to solve a system of equations. The following algorithm can be used to find \(x\). If the msets, \(\alpha, \beta, \gamma, \delta\), are of the appropriate sizes to determine the exact size of \(x\), then we know the exact number of steps required to solve for \(x\). If \(|\alpha| = |\beta|\), then there is no definite number of steps known, a priori. We know that a finite number of steps will be required. This derives from the fact that at each stage of the algorithm, at least one element from each side is removed. So after a finite number of steps, \(x^{(N)} = \emptyset\). As stated we do not know how many steps will be required.

Algorithm 8.39.

Suppose we want to solve \(\alpha \boxplus x \uplus \beta = \gamma \boxplus x \uplus \delta\). Assume that \(\alpha \cap \gamma = \emptyset\), and \(\beta \cap \delta = \emptyset\). Otherwise, these terms can be canceled from each side of the equation.

(1) \(x = x^{(0)}\), \(\beta^{(0)} = \beta\), \(\delta^{(0)} = \delta\)

(2) \(k = 1\)

(3) Let \(\hat{x} = \max\left(\frac{\delta_{\text{max}}}{\alpha_{\text{max}}}, \frac{\beta_{\text{max}}}{\gamma_{\text{max}}}\right)\)

(4) We rewrite \(x = (x^{(1)} \hat{x})\)

(5) Substitute into the equation \(\alpha \boxplus x \uplus \beta = \gamma \boxplus x \uplus \delta\) to get

(6) \(\alpha \boxplus (x^{(k)} \hat{x}) \uplus \beta^{(k-1)} = \gamma \boxplus (x^{(k)} \hat{x}) \uplus \delta^{(k-1)}\)

(7) \(\alpha x^{(k)} \uplus (\alpha \hat{x} \uplus \beta^{(k-1)}) = \gamma x^{(k)} \uplus (\gamma \hat{x} \uplus \delta^{(k-1)})\)

Cancel common elements.

(8) Rewrite as \(\alpha \boxplus x^{(k)} \uplus \beta^{(k)} = \gamma \boxplus x^{(k)} \uplus \delta^{(k)}\)
(9) If \( \beta^{(k)} = \delta^{(k)} = \emptyset \) then stop.

(10) If, at any time, the consistency condition fails then there is no solution. Stop.

(11) k = k + 1

(12) Goto Step (3).

This algorithm may be improved by also considering the minimum element of each side. This could improve the time of computation and also aid in approximating the number of steps necessary to complete the algorithm.

**Example 8.40.** Use Algorithm 8.39 to solve:

\[
\{7, 9\} x \cup \{15, \frac{63}{4}, 20\} = \{5, \frac{21}{4}\} x \cup \{27, 28, 36\} \tag{132}
\]

We go through the steps of the algorithm to get the solution.

\[
\hat{x} = \max \left( \frac{36}{9}, \frac{20}{4} \right) = \max \left( 4, \frac{80}{21} \right) = 4 \tag{133}
\]

\[
\{7, 9\} \{x^{(1)}, \hat{x}\} \cup \{15, 20, \frac{63}{4}\} = \{5, \frac{21}{4}\} \{x^{(1)}, \hat{x}\} \cup \{27, 28, 36\} \tag{134}
\]

\[
\{7, 9\} x^{(1)} \cup \{7, 9\} \{4\} \cup \{15, \frac{63}{4}, 20\} = \{5, \frac{21}{4}\} x^{(1)} \cup \{5, \frac{21}{4}\} \{4\} \{27, 28, 36\} \tag{135}
\]

\[
\{7, 9\} x^{(1)} \cup \{15, \frac{63}{4}, 20, 28, 36\} = \{5, \frac{21}{4}\} x^{(1)} \cup \{5, \frac{21}{4}\} \{20, 21, 27, 28, 36\} \tag{136}
\]

\[
\{7, 9\} x^{(1)} \cup \{15, \frac{63}{4}\} = \{5, \frac{21}{4}\} x^{(1)} \cup \{21, 27\} \tag{137}
\]

\[
\hat{x} = \max \left( \frac{27}{9}, \frac{63}{4} \right) = \max (3, 3) = 3 \tag{138}
\]

\[
\{7, 9\} \{x^{(2)}, \hat{x}\} \cup \{15, \frac{63}{4}\} = \{5, \frac{21}{4}\} \{x^{(2)}, \hat{x}\} \cup \{21, 27\} \tag{139}
\]
\[ \{7,9\}x^{(2)} \cup \{7,9\}\{3\} \cup \{15, \frac{63}{4}\} = \{5, \frac{21}{4}\}x^{(2)} \cup \{5, \frac{21}{4}\}\{3\} \cup \{21, 27\} \]  
(140)

\[ \{7,9\}x^{(2)} \cup \{15, \frac{63}{4}, 21, 27\} = \{5, \frac{21}{4}\}x^{(2)} \cup \{15, \frac{63}{4}, 21, 27\} \]  
(141)

\[ \{7,9\}x^{(2)} = \{5, \frac{21}{4}\}x^{(2)} \]  
(142)

\[ x^{(2)} = \emptyset \]  
(143)

Therefore, we have \( x = \{3,4\} \) as the solution to equation (132)  

8.7 Matrix Equations over \( \mathbb{R}^5 \)

In this section we investigate systems of equations over \( \mathbb{R}^5 \). The natural question may arise as to the amount of information which can be developed from the known results of Linear systems in the conventional algebra. In this section we investigate some of the elementary properties of Linear systems in \( \mathbb{R}^5 \). We start with a short overview of homogeneous systems and continue with an investigation of Cramer’s Rule and its relation to the system of nonhomogeneous equations.

**Homogeneous Systems**

**Proposition 8.1.** If \( a_1x_1 \cup a_2x_2 \cup \cdots \cup a_nx_n = \emptyset \), and \( x_i \neq \emptyset \) for all \( i \), then \( a_i = \emptyset \) for all \( i \).

There is a very close analogy between solving systems of equations over \( \mathbb{R}^5 \) and solving systems of equations over the nonnegative real numbers. Many of these results will involve graph theory as the matrix \( A \) is viewed as the adjacency matrix of a graph. The mset can be considered as the “weight” of the path in which the time for a “process” is broken into its constituent parts. For example, \( \{2,1\} \) is viewed as a weight of “3” which is separated into two sub-processes, one of weight=2 and one of weight=1.

The first system to consider is the homogeneous system of equations:

\[ Ax = \emptyset \]  
(144)

**Theorem 8.42.** If \( A \) is an irreducible \( n \times n \) mset matrix and \( Ax = \emptyset \), then \( x = \emptyset \).
Proof. Suppose \( x_k \neq \emptyset \). Then, for each \( i \),
\[
\emptyset = (Ax)_i = \bigcup_{j=1}^{n} a_{ij} x_j \geq a_{ik} x_k
\]
Therefore, \( a_{ik} = 0 \), for all \( i \). So \( A \) has a column equal to \( \emptyset \), and, hence, it is reducible. Therefore \( z = \emptyset \).

We include a few results which are quite useful in the theory of mset matrices. As we see the proofs of these results are almost identical with the proofs given in the theory of nonnegative matrices.

**Theorem 8.43.** If \( A \geq \emptyset \) and \( A \) is reducible, then
(a) \( A^k \) is reducible for all \( k \)
(b) \( \bigcup_k A^k \) is reducible.

**Proof.** Suppose \( A \approx \begin{bmatrix} B & C \\ 0 & D \end{bmatrix} \).
(a) \( A^k \approx \begin{bmatrix} B^k & \? \\ 0 & D^k \end{bmatrix} \)
and
(b) \( \bigcup_k A^k \approx \begin{bmatrix} \bigcup_k B^k & \? \\ 0 & \bigcup_k D^k \end{bmatrix} \)

**Theorem 8.44.** If \( A \) is an irreducible mset \( n \times n \) matrix, \( n \geq 2 \), and \( x \geq \emptyset \) with exactly \( k \) elements with are not \( \emptyset \), \( 1 \leq k \leq n-1 \), then \( (I \uplus A)x \) has more than \( k \) nonempty elements.

\[
\begin{bmatrix}
x_1 \\
\vdots \\
x_k \\
0 \\
\vdots \\
0
\end{bmatrix}, \text{ where } x_i \neq \emptyset;
\]

for \( 1 \leq i \leq k \).

So \( x \) has \( n-k \) “zero” elements. \( (I \uplus A)x = x \uplus Ax \) cannot have more than \( n-k \) zero elements. Suppose that \( (I \uplus A) \) has exactly \( n-k \) elements equal to \( \emptyset \). Therefore \( (Ax)_i = \emptyset \) whenever \( x_i = \emptyset \). Therefore \( (I \uplus A)x \) has as many zero elements as \( x \). So \( (Ax)_i = \emptyset \), for \( i = k+1, k+2, \ldots, n \).

\[
(Ax)_i = \sum_{j=1}^{n} a_{ij} x_j = \sum_{j=1}^{k} a_{ij} x_j = \emptyset
\]
(145)

Since \( x_j = \emptyset \), for \( 1 \leq j \leq k \) then \( a_{ij} = \emptyset \) for \( j = k+1, k+2, \ldots, n \). Therefore \( A \) is reducible, which is a contradiction. So \( (I \uplus A)x \) has more than \( k \) nonzero elements.
**Corollary 8.45.** If $A$ is an irreducible $n \times n$ mset matrix, and $\mathfrak{I} \geq \emptyset$, then $(I \Psi A)^{n-1} \mathfrak{I} > \emptyset$.

**Corollary 8.46.** If $A$ is an $n \times n$ mset matrix, then $A$ is irreducible if and only if $(I \Psi A)^{n-1} > \emptyset$.

**Proof.** The sufficiency follows from Corollary 8.45, and the necessity follows from Theorem 8.43. □

As with many of our results the following theorem can be used for the investigation into nonnegative matrices.

Let $A \geq 0, x \geq 0$, and consider the equation

$$Ax = 0, \quad (146)$$

We know that

$$A \approx_{\text{per}} \begin{bmatrix} X & 0 & X \newline 0 & X & 
\end{bmatrix} \quad \text{where} \quad \begin{cases} 
\text{anything} \\
X \text{ irreducible} \\
0 \ 1 \times 1 \ 0\text{-matrix}
\end{cases} \quad (147)$$

We first focus on $\ell_1$=first zero. Consider the sets

$$V_{\ell_1} \quad \rightarrow \quad \begin{cases} 
V_{\ell_1}^+ = \{ V_\ell | V_\ell \rightarrow V_{\ell_1} \} \\
V_{\ell_1}^- = \{ V_\ell | V_\ell \rightarrow V_{\ell_1} \}
\end{cases} \quad (148)$$

Matrix $A$ can then be permuted to the form

$$A \approx_{\text{per}} \begin{bmatrix} V_{\ell_1}^+ & V_{\ell_1} & V_{\ell_1}^- \newline V_{\ell_1}^+ & 0 & \alpha_{\ell_1} \newline V_{\ell_1}^- & 0 & 0 \end{bmatrix} \quad (149)$$

We can continue the above process to get a matrix of the form
The vector \( \mathbf{x} \) is partitioned conformally with \( A \): 
\[
\mathbf{x} = \begin{bmatrix} x_1 & y_1 & x_2 & y_2 & x_\ell \end{bmatrix}^T
\]

Consider the last equation in (146)

\[
\begin{bmatrix} M_{\ell 1} & \cdots & \cdots & M_{\ell k_\ell} \\
0 & \ddots & \ddots & \vdots \\
0 & \ddots & \ddots & \ddots \\
0 & \ddots & \ddots & \ddots 
\end{bmatrix}
\begin{bmatrix} x_1 \\ \vdots \\ x_{\ell} 
\end{bmatrix} = \begin{bmatrix} M_{\ell 1} \\ \vdots \\ M_{\ell k_\ell} \end{bmatrix}
\]

(151)

Since \( M_\ell \) is irreducible then \( x_\ell = 0 \).

Continuing backwards, we get that all \( x_i \)'s must equal 0.

Hence, the matrix \( A \) must be nilpotent and can be replaced by the matrix

![Matrix](image-url)
\[
\begin{bmatrix}
0 & a_{12} & a_{13} & \cdots & a_{1\ell} \\
0 & a_{23} & a_{24} & \cdots & a_{2\ell} \\
\vdots & & & \ddots & \vdots \\
0 & & & & a_{\ell-1,\ell} \\
0 & & & & 0
\end{bmatrix}
\begin{bmatrix}
y_1 \\
y_2 \\
\vdots \\
y_{\ell-1} \\
y_{\ell}
\end{bmatrix}
= \begin{bmatrix}
0 \\
0 \\
\vdots \\
0 \\
0
\end{bmatrix}
\] (152)

So if there is a path from \( \mathcal{P}_i \) to \( \mathcal{P}_j \) then the associated \( y_i \)'s are equal to zero. For example if there is a path from \( \mathcal{P}_3 \) to \( \mathcal{P}_4 \) then \( \alpha_{34} \neq 0 \) which implies that \( y_4 = 0 \). So if there is a path from \( \mathcal{P}_j \) to \( \mathcal{P}_j \) then \( y_j = 0 \).

Therefore a column of zeros imply that a nonzero solution exists.

**Nonhomogeneous Systems**

In this section we consider matrices over \( 3^{\mathbb{R}^+} \). The aim is to simplify the work in the \( \mathcal{M}^* \) algebra. Many results can be shown in a general semiring. In particular, see Theorem 8.101.

Suppose that we are given a mset equation

\[ Ax = b. \] (153)

One of our main methods of solution for the nonhomogeneous equation, (153), is through Cramer’s Rule.

**Example 8.47** (Cramer’s Rule). We look at the \( 2 \times 2 \) system of msets over \( 3^{\mathbb{R}^+} \) first. All elements of each mset is positive in this first example.

Solve the following system of equations.

\[
\begin{bmatrix}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{bmatrix}
\begin{bmatrix}
x \\
y
\end{bmatrix}
= \begin{bmatrix}
b_1 \\
b_2
\end{bmatrix}
\] (154)

This leads to the system:

\[ a_{11}x \uplus a_{12}y = b_1 \] (155)

\[ a_{21}x \uplus a_{22}y = b_2 \] (156)

Multiply Equation 155 by \( a_{22} \), and multiply Equation 156 by \( a_{12} \).

\[ a_{22}a_{11}x \uplus a_{22}a_{12}y = a_{22}b_1 \] (157)

\[ a_{12}a_{21}x \uplus a_{12}a_{22}y = a_{12}b_2 \] (158)

Combining these equations yields:

\[ a_{22}a_{11}x \uplus a_{22}a_{12}y \uplus a_{12}b_2 = a_{12}a_{21}x \uplus a_{12}a_{22}y \uplus a_{22}b_1 \] (159)
We can cancel \( a_{12} a_{22} y \) and get the equation:

\[
  a_{22} a_{11} x \cup a_{12} b_2 = a_{12} a_{21} x \cup a_{22} b_1
\] (160)

Likewise, we can multiply Equation 155 by \( a_{21} \), and multiply Equation 156 by \( a_{11} \). Combine the two equations, and cancel the term \( a_{11} a_{21} x \) from each side. This leads to the equation:

\[
  a_{11} a_{22} y \cup a_{21} b_1 = a_{12} a_{21} y \cup a_{11} b_2
\] (161)

So, we get the system of equations:

\[
  a_{11} a_{22} x \cup a_{12} b_2 = a_{12} a_{21} x \cup a_{22} b_1
\] (162)

\[
  a_{11} a_{22} y \cup a_{21} b_1 = a_{12} a_{21} y \cup a_{11} b_2
\] (163)

Equation (162) is an equation in “\( x \)” only, and Equation (163) is an equation in “\( y \)” only. This can be viewed, at least for now, as Consistency Conditions for the system. If we use the sizes of the msets, we get four consistency conditions from Equations (155) and (156), and Equations (162) and (163).

\[
  |a_{11}| \cdot |x| + |a_{12}| \cdot |y| = |b_1|
\] (164)

\[
  |a_{21}| \cdot |x| + |a_{22}| \cdot |y| = |b_2|
\] (165)

\[
  |a_{11} a_{22}| \cdot |x| + |a_{12} b_2| = |a_{12} a_{21}| \cdot |x| + |a_{22} b_1|
\] (166)

\[
  |a_{11} a_{22}| \cdot |y| + |a_{21} b_1| = |a_{12} a_{21}| \cdot |y| + |a_{11} b_2|
\] (167)

So, we have taken the system of equations and separated the equations so that each equation has only one unknown. The equations seem beyond an algebraic solution although Algorithm (8.39) can be used to solve for the unknown.

The next part of this problem is to show that if we are given the system of equations, Equations (162) and (163), then we can go back to the original system of equations, namely Equation (154).

Given the equations in (162) and (163), we multiply equation (162) by \( a_{11} \), and multiply equation (163) by \( a_{12} \) to get:

\[
  a_{11} a_{11} a_{22} x \cup a_{11} a_{12} b_2 = a_{11} a_{12} a_{21} x \cup a_{11} a_{22} b_1
\] (168)

\[
  a_{11} a_{22} a_{12} y \cup a_{12} a_{21} b_1 = a_{12} a_{12} a_{21} y \cup a_{11} a_{12} b_2
\] (169)

Add the left sides of the equations and add the right sides of the equations, cancel the like term of \( a_{11} a_{12} b_2 \), and factor the remaining terms to get:

\[
  a_{11} a_{22}(a_{11} x \cup a_{12} y) \cup a_{12} a_{21} b_1 = a_{12} a_{21}(a_{11} x \cup a_{12} y) \cup a_{11} a_{22} b_1
\] (170)
Likewise, we could also multiply equation (162) by $a_{21}$, multiply equation (163) by $a_{22}$, add together as above, cancel the common term of $a_{21}a_{22}b_1$, and factor the remaining terms to get:

$$a_{11}a_{22}(a_{21}x \uplus a_{22}y) \uplus a_{12}a_{21}b_2 = a_{12}a_{21}(a_{21}x \uplus a_{22}y) \uplus a_{11}a_{22}b_2$$  \hfill (171)

Consider Equation (170). Using Lemma 8.27, with $\alpha = a_{11}a_{22}$, $\beta = a_{12}a_{21}$, $u = a_{11}x \uplus a_{12}y$, and $v = b_1$, we get that either $a_{11}a_{22} = a_{12}a_{21}$, or $a_{11}x \uplus a_{12}y = b_1$.

Likewise for Equation (171), we get that either $a_{11}a_{22} = a_{12}a_{21}$, or $a_{21}x \uplus a_{22}y = b_2$.

So, we see that starting with equations (162) and (163), we have either that $a_{11}a_{22} = a_{12}a_{21}$ or $Ax = b$, the system in Equation (154).

The $3 \times 3$ case of Cramer’s Rule is quite illustrative. We now consider this case.

**Example 8.48.** Solve the following system of equations of msets over $3^{\mathbb{R}^+}$. Again, we note that all elements are msets of positive elements.

$$\begin{bmatrix}
  a_{11} & a_{12} & a_{13} \\
  a_{21} & a_{22} & a_{23} \\
  a_{31} & a_{32} & a_{33}
\end{bmatrix} \bigg|\bigg. \begin{bmatrix}
  x_1 \\
  x_2 \\
  x_3
\end{bmatrix} = \begin{bmatrix}
  b_1 \\
  b_2 \\
  b_3
\end{bmatrix}$$  \hfill (172)

The three equations are:

$$a_{11}x_1 \uplus a_{12}x_2 \uplus a_{13}x_3 = b_1$$  \hfill (173)
$$a_{21}x_1 \uplus a_{22}x_2 \uplus a_{23}x_3 = b_2$$  \hfill (174)
$$a_{31}x_1 \uplus a_{32}x_2 \uplus a_{33}x_3 = b_3$$  \hfill (175)

If we multiply Equation (173) by $a_{23}$, and multiply Equation (174) by $a_{13}$, combine the two equations, and cancel the common multisets of $a_{13}a_{23}x_3$ to get:

$$a_{11}a_{23}x_1 \uplus a_{12}a_{23}x_2 \uplus a_{13}b_2 = a_{13}a_{21}x_1 \uplus a_{13}a_{22}x_2 \uplus a_{23}b_1$$  \hfill (176)

Likewise, using Equations (174) and (175), we get:

$$a_{21}a_{33}x_1 \uplus a_{22}a_{33}x_2 \uplus a_{23}b_3 = a_{23}a_{31}x_1 \uplus a_{23}a_{32}x_2 \uplus a_{33}b_2$$  \hfill (177)

Likewise, using Equations (173) and (175), we get:

$$a_{13}a_{31}x_1 \uplus a_{13}a_{32}x_2 \uplus a_{33}b_1 = a_{11}a_{33}x_1 \uplus a_{12}a_{33}x_2 \uplus a_{13}b_3$$  \hfill (178)

Multiplying Equation (176) by $a_{32}$, Equation (177) by $a_{12}$, and Equation (178) by $a_{22}$ yields:
\[ a_{11}a_{23}a_{32}x_1 \oplus a_{12}a_{23}a_{32}x_2 \oplus a_{13}a_{32}b_2 = a_{13}a_{21}a_{32}x_1 \oplus a_{13}a_{22}a_{32}x_2 \oplus a_{23}a_{32}b_1 \] (179)

\[ a_{21}a_{33}a_{12}x_1 \oplus a_{22}a_{33}a_{12}x_2 \oplus a_{23}a_{12}b_3 = a_{23}a_{31}a_{12}x_1 \oplus a_{23}a_{32}a_{12}x_2 \oplus a_{33}a_{12}b_2 \] (180)

\[ a_{13}a_{31}a_{22}x_1 \oplus a_{13}a_{32}a_{22}x_2 \oplus a_{13}a_{22}b_1 = a_{11}a_{33}a_{22}x_1 \oplus a_{12}a_{33}a_{22}x_2 \oplus a_{13}a_{22}b_3 \] (181)

If we add the LHS of Equations (179), (180), and (181), and set this equal to the sum of the RHS of the same equations and cancel equal multisets on each side then we get the equation:

\[
(a_{11}a_{23}a_{32} \oplus a_{22}a_{13}a_{31} \oplus a_{33}a_{12}a_{21}) x_1 \oplus a_{22}a_{33}b_1 \oplus a_{13}a_{32}b_2 \oplus a_{12}a_{23}b_3 \\
= (a_{11}a_{22}a_{33} \oplus a_{12}a_{23}a_{31} \oplus a_{13}a_{32}a_{21}) x_1 \oplus a_{23}a_{32}b_1 \oplus a_{12}a_{33}b_2 \oplus a_{13}a_{22}b_3
\] (182)

We note that this is an equation with only one unknown, namely \( x_1 \).

We can continue to do the same calculations with the original equations ((173), (174), (175)) to eliminate \( x_2 \), and again to eliminate \( x_3 \), and we get the following three equations:

\[
(a_{11}a_{23}a_{32} \oplus a_{22}a_{13}a_{31} \oplus a_{33}a_{12}a_{21}) x_1 \oplus a_{22}a_{33}b_1 \oplus a_{13}a_{32}b_2 \oplus a_{12}a_{23}b_3 \\
= (a_{11}a_{22}a_{33} \oplus a_{12}a_{23}a_{31} \oplus a_{13}a_{32}a_{21}) x_1 \oplus a_{23}a_{32}b_1 \oplus a_{12}a_{33}b_2 \oplus a_{13}a_{22}b_3
\] (182)

\[
(a_{11}a_{23}a_{32} \oplus a_{22}a_{13}a_{31} \oplus a_{33}a_{12}a_{21}) x_2 \oplus a_{23}a_{33}b_1 \oplus a_{11}a_{33}b_2 \oplus a_{13}a_{21}b_3 \\
= (a_{11}a_{22}a_{33} \oplus a_{12}a_{23}a_{31} \oplus a_{13}a_{32}a_{21}) x_2 \oplus a_{21}a_{33}b_1 \oplus a_{13}a_{31}b_2 \oplus a_{11}a_{23}b_3
\] (183)

\[
(a_{11}a_{23}a_{32} \oplus a_{22}a_{13}a_{31} \oplus a_{33}a_{12}a_{21}) x_3 \oplus a_{21}a_{33}b_1 \oplus a_{31}a_{12}b_2 \oplus a_{11}a_{22}b_3 \\
= (a_{11}a_{22}a_{33} \oplus a_{12}a_{23}a_{31} \oplus a_{13}a_{32}a_{21}) x_3 \oplus a_{22}a_{33}b_1 \oplus a_{11}a_{32}b_2 \oplus a_{12}a_{21}b_3
\] (184)

**Note 8.49.** The three equations (182), (183), (184), derived from Cramer’s Rule can not be simplified further. Each equation is an equation in only one variable, and once the equation is translated back into the semiring \( \mathbb{R}^+ \), it can be solved for \( x_i \).

Although \( \mathbb{R}^+ \) and \( 3^\mathbb{R}^+ \) do not have a “minus”, we can manipulate the expressions identically with expressions in \( (\mathbb{R}, +, \times) \) in calculating the determinants. When complete the terms containing a minus-sign are moved to the opposite side of the equation. This is equivalent to the ordinary
Cramer’s Rule if we write:

\[
\begin{align*}
x_1 &= \frac{b_1 a_{12} a_{13} - b_2 a_{12} a_{13} - b_3 a_{12} a_{13}}{a_{11} a_{12} a_{13}} \\
x_2 &= \frac{a_{11} b_1 a_{13} - a_{21} b_2 a_{13} - a_{31} b_3 a_{13}}{a_{11} a_{12} a_{13}} \\
x_3 &= \frac{a_{11} a_{12} b_1 - a_{21} a_{12} b_2 - a_{31} a_{12} b_3}{a_{11} a_{12} a_{13}}
\end{align*}
\]

(185)

where, in calculating the “determinants”, we keep the “positive” and “negative” terms separate. In this manner we get:

\[
x_i = \frac{N_i^+ - N_i^-}{M^+ - M^-} \iff M^+ x_i + N_i^- = M^- x_i + N_i^+
\]

(186)

Here, we have \( M^+ = |A|^+, \quad M^- = |A|^- \), \( N_i^+ = |A_i(b)|^+ \), \( N_i^- = |A_i(b)|^- \). We use the notation \( A_i(b) \) to represent the matrix \( A \) where the \( i \)th column is replaced by \( b \).

So, we can write Equation (186) as:

\[
|A|^+ x_i + |A_i(b)|^- = |A|^- x_i + |A_i(b)|^+
\]

(187)

We briefly describe the system of algebraic manipulations required to show that Equations (182), (183), (184) are equivalent to the system of equations in Equation (172).

Multiply:

(1) Equation (182) by \( a_{11} \),

(2) Equation (183) by \( a_{12} \), and

(3) Equation (184) by \( a_{13} \)

Set the sum of the left sides of the resulting equations equal to the sum of the right sides of the equations. Cancel the terms which are the same on each side, and factor the result. This leads to the following equation:

\[
a_{11} a_{12} a_{23} a_{32} x_1 + a_{11} a_{22} a_{13} a_{31} x_1 + a_{11} a_{33} a_{21} a_{32} x_1 + a_{11} a_{22} a_{33} b_1 + a_{11} a_{13} a_{32} b_2 + a_{11} a_{12} a_{23} b_3 \\
+ a_{12} a_{13} a_{23} a_{32} x_2 + a_{12} a_{22} a_{13} a_{31} x_2 + a_{12} a_{33} a_{13} a_{32} x_2 + a_{12} a_{23} a_{31} b_1 + a_{12} a_{11} a_{33} b_2 + a_{12} a_{13} a_{21} b_3 \\
+ a_{13} a_{12} a_{23} a_{32} x_3 + a_{13} a_{22} a_{13} a_{31} x_3 + a_{13} a_{33} a_{21} a_{32} x_3 + a_{13} a_{23} a_{31} b_1 + a_{13} a_{11} a_{32} b_2 + a_{13} a_{12} a_{23} b_3
\]

= \( a_{11} a_{12} a_{23} a_{31} x_1 + a_{11} a_{22} a_{13} a_{32} x_1 + a_{11} a_{33} a_{12} a_{32} x_1 + a_{11} a_{23} a_{31} b_1 + a_{11} a_{13} a_{32} b_2 + a_{11} a_{12} a_{23} b_3 \\
+ a_{12} a_{13} a_{31} a_{32} x_2 + a_{12} a_{33} a_{13} a_{21} x_2 + a_{12} a_{31} a_{13} a_{32} x_2 + a_{12} a_{31} a_{13} b_1 + a_{12} a_{11} a_{32} b_2 + a_{12} a_{13} a_{22} b_3 \\
+ a_{13} a_{12} a_{31} a_{32} x_3 + a_{13} a_{12} a_{23} a_{31} x_3 + a_{13} a_{23} a_{13} a_{32} x_3 + a_{13} a_{23} a_{31} b_1 + a_{13} a_{11} a_{32} b_2 + a_{13} a_{12} a_{23} b_3
\]

(188)
which can be factored as:

\[
(a_{11}a_{23}a_{32} \uplus a_{13}a_{22}a_{31} \uplus a_{12}a_{21}a_{33}) (a_{11}x_1 \uplus a_{12}x_2 \uplus a_{13}x_3)
\]

\[
\uplus (a_{11}a_{22}a_{33} \uplus a_{12}a_{23}a_{31} \uplus a_{13}a_{32}a_{21}) b_1
\]

\[
= (a_{11}a_{22}a_{33} \uplus a_{12}a_{23}a_{31} \uplus a_{13}a_{32}a_{21}) (a_{11}x_1 \uplus a_{12}x_2 \uplus a_{13}x_3)
\]

\[
\uplus (a_{11}a_{23}a_{32} \uplus a_{13}a_{22}a_{31} \uplus a_{12}a_{21}a_{33}) b_1
\]

(189)

Again, using Lemma 8.27, we see that either

\[
a_{11}a_{23}a_{32} \uplus a_{13}a_{22}a_{31} \uplus a_{12}a_{21}a_{33} = a_{11}a_{22}a_{33} \uplus a_{12}a_{23}a_{31} \uplus a_{13}a_{32}a_{21}
\]

(190)

or

\[
a_{11}x_1 \uplus a_{12}x_2 \uplus a_{13}x_3 = b_1
\]

(191)

Equation (190) corresponds to having a “determinant” equal to zero, and Equation (191) is equivalent to the first equation of the system of equations in Equation (172).

The other two equations can be found using manipulations similar to those above.

This example has shown that the 3×3 system of positive-multiset elements is equivalent to the equations defined by Cramer’s Rule or

\[
a_{11}a_{23}a_{32} \uplus a_{13}a_{22}a_{31} \uplus a_{12}a_{21}a_{33} = a_{11}a_{22}a_{33} \uplus a_{12}a_{23}a_{31} \uplus a_{13}a_{32}a_{21}.
\]

Definition 8.50. Here, we define:

\[
\text{par}(n) = \begin{cases} 
  "^+" & \text{if } n \text{ is even} \\
  "^-" & \text{if } n \text{ is odd}
\end{cases}
\]

Example 8.51. Let us consider Example 8.48 over \(\mathbb{R}^+\) once again. We consider the system of manipulations required in the second part of that example in a much more systematic way that can easily be extended to larger systems of equations. You may see Theorem 8.101 for the general case over semirings.

Expand by first column:

\[
\begin{align*}
M^+ &= a_{11}M_{11}^+ \uplus a_{21}M_{21}^- \uplus a_{31}M_{31}^+ = \biguplus_{i=1}^{3} a_{i1}M_{ii}^{\text{par}(i+1)} \\
M^- &= a_{11}M_{11}^- \uplus a_{21}M_{21}^+ \uplus a_{31}M_{31}^- = \biguplus_{i=1}^{3} a_{i1}M_{ii}^{\text{par}(i)} \\
N_1^+ &= b_1M_{11}^+ \uplus b_2M_{21}^- \uplus b_3M_{31}^+ = \biguplus_{i=1}^{3} b_iM_{ii}^{\text{par}(i+1)} \\
N_1^- &= b_1M_{11}^- \uplus b_2M_{21}^+ \uplus b_3M_{31}^- = \biguplus_{i=1}^{3} b_iM_{ii}^{\text{par}(i)}
\end{align*}
\]

(192)
Expand by second column:

\[
\begin{aligned}
M^+ &= a_{12} M_{12}^+ \uplus a_{22} M_{22}^+ \uplus a_{32} M_{32}^+ = \frac{3}{i=1} a_{12} M_{12}^{par(i)} \\
M^- &= a_{12} M_{12}^+ \uplus a_{22} M_{22}^- \uplus a_{32} M_{32}^- = \frac{3}{i=1} a_{12} M_{12}^{par(i+1)} \\
N_2^+ &= b_1 M_{12}^+ \uplus b_2 M_{22}^+ \uplus b_3 M_{32}^+ = \frac{3}{i=1} b_1 M_{12}^{par(i)} \\
N_2^- &= b_1 M_{12}^+ \uplus b_2 M_{22}^- \uplus b_3 M_{32}^- = \frac{3}{i=1} b_1 M_{12}^{par(i+1)}
\end{aligned}
\]  
(193)

Expand by third column:

\[
\begin{aligned}
M^+ &= a_{13} M_{13}^+ \uplus a_{23} M_{23}^- \uplus a_{33} M_{33}^+ = \frac{3}{i=1} a_{13} M_{13}^{par(i+1)} \\
M^- &= a_{13} M_{13}^+ \uplus a_{23} M_{23}^+ \uplus a_{33} M_{33}^- = \frac{3}{i=1} a_{13} M_{13}^{par(i)} \\
N_3^+ &= b_1 M_{13}^+ \uplus b_2 M_{23}^+ \uplus b_3 M_{33}^+ = \frac{3}{i=1} b_1 M_{13}^{par(i+1)} \\
N_3^- &= b_1 M_{13}^+ \uplus b_2 M_{23}^- \uplus b_3 M_{33}^- = \frac{3}{i=1} b_1 M_{13}^{par(i)}
\end{aligned}
\]  
(194)

Rewriting Equation (186) as three equations, we get:

\[
\begin{aligned}
M^+ x_1 \uplus N_1^- &= M^- x_1 \uplus N_1^+ \\
M^+ x_2 \uplus N_2^- &= M^- x_2 \uplus N_2^+ \\
M^+ x_3 \uplus N_3^- &= M^- x_3 \uplus N_3^+
\end{aligned}
\]  
(195a,b,c)

If we want to use these equations ((195a),(195b), and (195c)) to get the first equation of the system (172), then we consider:

\[
a_{11} \boxtimes (195a) \uplus a_{12} \boxtimes (195b) \uplus a_{13} \boxtimes (195c)
\]  
(196)

where the left sides of the three products are added together and the right sides of the equations are added together.

This leads to the following very long equation:

\[
\begin{aligned}
a_{11} a_{11} M_{11}^+ \uplus a_{11} a_{21} M_{21}^+ \uplus a_{11} a_{31} M_{31}^+ \uplus a_{12} a_{12} M_{12}^+ \uplus a_{12} a_{22} M_{22}^+ \uplus a_{12} a_{32} M_{32}^+ \\
\uplus a_{13} a_{13} M_{13}^+ \uplus a_{13} a_{23} M_{23}^+ \uplus a_{13} a_{33} M_{33}^+ \uplus a_{11} b_1 M_{11}^- \uplus a_{11} b_1 M_{21}^+ \uplus a_{11} b_1 M_{31}^- \\
\uplus a_{12} b_2 M_{12}^+ \uplus a_{12} b_2 M_{22}^+ \uplus a_{12} b_2 M_{32}^+ \uplus a_{13} b_3 M_{13}^- \uplus a_{13} b_3 M_{23}^+ \uplus a_{13} b_3 M_{33}^- \\
\uplus a_{11} a_{11} M_{11}^- \uplus a_{11} a_{21} M_{21}^- \uplus a_{11} a_{31} M_{31}^- \uplus a_{12} a_{12} M_{12}^- \uplus a_{12} a_{22} M_{22}^- \uplus a_{12} a_{32} M_{32}^+ \\
\uplus a_{13} a_{13} M_{13}^- \uplus a_{13} a_{23} M_{23}^- \uplus a_{13} a_{33} M_{33}^- \uplus a_{11} b_1 M_{11}^- \uplus a_{11} b_1 M_{21}^+ \uplus a_{11} b_1 M_{31}^- \\
\uplus a_{12} b_2 M_{12}^+ \uplus a_{12} b_2 M_{22}^+ \uplus a_{12} b_2 M_{32}^+ \uplus a_{13} b_3 M_{13}^+ \uplus a_{13} b_3 M_{23}^+ \uplus a_{13} b_3 M_{33}^-
\end{aligned}
\]  
(197)

In this case the terms with \(b_2\) and \(b_3\) must be the same. If we consider the part of Equation (197) that have the terms containing \(b_2\), we get the following subequation:

\[
(a_{11} M_{21}^+ \uplus a_{12} M_{22}^- \uplus a_{13} M_{23}^-) b_2 = (a_{11} M_{21}^- \uplus a_{12} M_{22}^+ \uplus a_{13} M_{23}^+) b_2
\]  
(198)

85
These two sides are equal from the method of False Cofactor Expansion, and cancel from each side of Equation (197). Likewise, we can show, similarly, that the terms involving \( b_3 \) will also cancel from each side of the equation. This same method works for the other two equations in the system. Therefore, we have seen that Equation (172) is equivalent to the set of solutions to Equations ((182), (183), (184)).

**Another Mapping**

As we look at the progression from Equation (111) to Equation (114), we notice a method that can be used to convert an equation with one variable (an mset) into a \( 2 \times 2 \) system which has all mset elements positive. This same method can be used to change a \( n \times n \) system into a \( (2n) \times (2n) \) system which has all elements positive. With this in mind, we may further our investigation by considering the following function \( \Psi(\alpha) \).

**Definition 8.52.** Suppose \( \alpha = (\alpha^+, \alpha^-) \in \mathbb{R} \). Define:

\[
\Psi(\alpha) = \begin{bmatrix} \alpha^+ & -\alpha^- \\ -\alpha^- & \alpha^+ \end{bmatrix}
\] (199)

**Proposition 8.53.** We list some properties of this mapping. Let \( \alpha, \beta \in 3^\mathbb{R} \), and \( c \in \mathbb{R} \).

1. \( \Psi(\alpha \oplus \beta) = \Psi(\alpha) \oplus \Psi(\beta) \)
2. \( \Psi(\alpha \boxtimes \beta) = \Psi(\alpha) \boxtimes \Psi(\beta) \)
3. \( \Psi(c \boxtimes \alpha) = \begin{cases} 
\Psi(\{ca^+, ca^-\}) = c\Psi(\alpha) & \text{if } c > 0 \\
\Psi(\{ca^-, ca^+\}) = c\Psi(\alpha) & \text{if } c < 0 
\end{cases} \)
4. \( \Psi(\alpha) = \begin{bmatrix} \emptyset & \emptyset \\
\emptyset & \emptyset \end{bmatrix} \iff \alpha = \emptyset \)
5. \( \Psi(\alpha) = \Psi(\beta) \iff \begin{bmatrix} \alpha^+ & -\alpha^- \\
-\alpha^- & \alpha^+ \end{bmatrix} = \begin{bmatrix} \beta^+ & -\beta^- \\
-\beta^- & \beta^+ \end{bmatrix} \iff \alpha = \beta \)

With the results of this section at our disposal we can show that Cramer’s Rule works in the case of general systems of equations over \( 3^\mathbb{R} \) with the aid of the following theorem.

**Theorem 8.54.** If \( Ax = b \) has a solution, then the system is equivalent to the system of Cramer’s Rule equations, and, conversely, a system of Cramer’s Rule equations is equivalent to the system \( Ax = b \). Here \( A \in 3^\mathbb{R}_{n \times n} \), \( x \in 3^\mathbb{R}_{n \times 1} \), and \( b \in 3^\mathbb{R}_{n \times 1} \).
Proof. Suppose

\[
\begin{bmatrix}
  a_{11} & \cdots & a_{1n} \\
  \vdots & \ddots & \vdots \\
  a_{n1} & \cdots & a_{nn}
\end{bmatrix}
\begin{bmatrix}
  x_1 \\
  \vdots \\
  x_n
\end{bmatrix}
= 
\begin{bmatrix}
  b_1 \\
  \vdots \\
  b_n
\end{bmatrix}
\]

We apply \( \Psi \) to the system to get the \((2n) \times (2n)\) system:

\[
\begin{bmatrix}
  a_{11} & -a_{11} & \cdots & a_{1n} & -a_{1n} \\
  -a_{11} & a_{11} & \cdots & -a_{1n} & a_{1n} \\
  \vdots & \vdots & \ddots & \vdots & \vdots \\
  a_{n1} & -a_{n1} & \cdots & a_{nn} & -a_{nn} \\
  -a_{n1} & a_{n1} & \cdots & -a_{nn} & a_{nn}
\end{bmatrix}
\begin{bmatrix}
  x_1 \\
  \vdots \\
  x_n \\
  \vdots \\
  x_n
\end{bmatrix}
= 
\begin{bmatrix}
  b_1 \\
  \vdots \\
  b_1 \\
  \vdots \\
  b_1
\end{bmatrix}
\]

Although Equation (201) represents two separate systems of equations, it can be shown that the two systems are equivalent by considering the block-diagonal permutation matrix \( P = \)

\[
\begin{bmatrix}
  0 & 1 & \cdots & 0 & 0 \\
  1 & 0 & \cdots & 0 & 0 \\
  \vdots & \vdots & \ddots & \vdots & \vdots \\
  0 & 0 & \cdots & 1 & 0 \\
  0 & 0 & \cdots & 1 & 0
\end{bmatrix}
\]

\(2n \times 2n\)

From this we get a system of \( 2n \) equations associated with Cramer’s Rule, in which each equation contains only 1 variable. So we see that:

Equation (200) \iff Equation (201) \iff Cramer’s Rule system of equations – Equation (187).

\qed

8.8 Polynomials in \( 3^S \)

In this section we investigate some of the properties of polynomial forms over \( 3^S \), or \( 3^S[x] \).

**Definition 8.55.** A polynomial \( p \in 3^S[x] \) is an ordered list, with each element from \( 3^S \).

\( p=(p_0, p_1, \ldots, p_n, \emptyset, \ldots, \emptyset) \), where \( p_i \in 3^S \).

We may write the polynomial as \( p_0 \uplus p_1 \lambda \uplus p_2 \lambda^2 \uplus \cdots \uplus p_n \lambda^n \), where \( \lambda \) is a “place holder”.

The degree of \( p \), written \( \partial p \), is \( n \).

**Definition 8.56 (Addition).** If \( p, q \in 3^S[x] \), then:

\( p \oplus q \equiv (p_0 \uplus q_0, p_1 \uplus q_1, \ldots, p_n \uplus q_n, \ldots) \).
**Proposition 8.57.** The following are properties of addition in $3^5[x]$.

1. Addition is closed in $3^5[x]$.
2. Addition is commutative, since $\oplus$ is commutative.
3. The empty polynomial $\emptyset(x) = (\emptyset, \emptyset, \ldots, \emptyset) = \emptyset \oplus \emptyset \oplus \emptyset \lambda^2, \ldots$ is the additive identity.
4. Addition is associative, since $\oplus$ is associative.

**Definition 8.58 (Scalar Multiplication).** If $\gamma \in 3^5$, and $p \in 3^5[x]$, then

$$\gamma \circ p = (\gamma \otimes p_0, \gamma \otimes p_1, \ldots, \gamma \otimes p_n, \emptyset, \ldots)$$

**Proposition 8.59.** If $\gamma, \delta \in 3^5$, and $p, q \in 3^5[x]$, then

1. $\gamma \circ (p \oplus q) = \gamma \circ p \oplus \gamma \circ q$
2. $(\gamma \oplus \delta) \circ p = \gamma \circ p \oplus \delta \circ p$
3. $\{1\} \circ p = p$

**Definition 8.60 (Polynomial Multiplication).** If $p, q \in 3^5[x]$, then $p \ast q = s = (s_1, s_2, \ldots, s_n, \ldots)$, where $s_k = p_0 \otimes q_k \oplus p_1 \otimes q_{k-1} \oplus \cdots \oplus p_k \otimes q_0$

This is just the usual definition of polynomial multiplication.

**Example 8.61.**

$$(p_0, p_1, p_2) \ast (q_0, q_1, q_2)$$  

$= (p_0 \otimes q_0, p_0 \otimes q_1 \oplus p_1 \otimes q_0, p_0 \otimes q_2 \oplus p_1 \otimes q_1 \oplus p_2 \otimes q_0, p_1 \otimes q_2 \oplus p_2 \otimes q_1, p_2 \otimes q_2)$$

**Proposition 8.62.** The following are some properties of multiplication of polynomials in $3^5[x]$.

1. $\ast$ is commutative since $\otimes$ is commutative.
   $$p \ast q = q \ast p.$$
2. $\ast$ is associative.
   $$p \ast (q \ast r) = (p \ast q) \ast r$$
   This follows from the associativity of matrix multiplication.
3. $\ast$ is distributive over $\oplus$.
   $$p \ast (q \oplus r) = p \ast q \oplus p \ast r$$
4. If $\gamma \in S$, then $\gamma \ast (p \ast q) = (\gamma \ast p) \ast q$

We can define the following Evaluation Map.
Definition 8.63. Given $A \in S_{n \times n}$, define

$$\varphi_A(p) = p_0 \boxtimes I_N \uplus p_1 \boxtimes A \uplus p_2 \boxtimes A^2 \cdots p_n \boxtimes A^n$$  \hfill (202)

Proposition 8.64. The following are some properties of the evaluation map.

(1)

$$\varphi_A(p \oplus q) = \varphi_A(p_0 \uplus q_0, p_1 \uplus q_1, \ldots)$$

$$= (p_0 \uplus q_0) I \uplus (p_1 \uplus q_1) A \uplus \cdots$$

$$= (p_0 I \uplus p_1 A \uplus p_2 A^2 \uplus \cdots) \uplus (q_0 I \uplus q_1 A \uplus q_2 A^2 \uplus \cdots)$$

$$= \varphi_A(p) \uplus \varphi_A(q)$$  \hfill (203)

(2)

$$\varphi_A(\gamma * p) = \varphi_A(\gamma \boxtimes p_0, \gamma \boxtimes p_1, \ldots)$$

$$= (\gamma \boxtimes p_0) I \uplus (\gamma \boxtimes p_1) A \uplus \cdots$$

$$= \gamma \boxtimes (p_0 I \uplus p_1 A \uplus p_2 A^2 \uplus \cdots)$$

$$= \gamma \boxtimes \varphi_A(p)$$  \hfill (204)

(3)

$$\varphi_A(p * q) = \varphi_A(p) \boxtimes \varphi_A(q)$$  \hfill (205)

8.9 The Characteristic Polynomial in the Mset Algebra

We can convert the problem of equating the sums on each side of an equation into a problem of set inclusion, namely, showing that the msets on each side of the equation sign equal (contain exactly the same elements). We will use the mset Algebra from the previous section to prove the main result of this section.

Suppose that we are given a set $S$, along with two binary operations:

(a) $\oplus$, which is associative and commutative, with additive identity.

(b) $\boxtimes$, which is associative and commutative, with multiplicative identity.

(c) $\boxtimes$ is distributive over $\oplus$.

A matrix, $A \in S_{n \times n}$, can be viewed as the adjacency matrix of a weighted directed graph. Given two matrices $A, B \in S_{n \times n}$, then define:

89
1. \([A \oplus B]_{ij} = A_{ij} \oplus B_{ij}\)

2. \([A \odot B]_{ij} = \bigoplus_{k=1}^{n} (A_{ik} \odot A_{kj})\)

3. \([A^n]_{ij} = \bigoplus_{k_1=1}^{n} \bigoplus_{k_2=1}^{n} \cdots \bigoplus_{k_{m-1}=1}^{n} (A_{ik_1} \odot A_{k_1k_2} \odot \cdots \odot A_{k_{m-1}j})\)

**Notation**

Let \(A \in S_{n \times n}\). Let \(S_n = \{1, 2, \ldots, n\}\). Let \(C^k_n\) be the set of all permutations of \(k\) elements from \(S_n\). Let \(A^\varphi\) be the submatrix of \(A\) obtained by taking the rows of \(A\) indexed by \(\varphi\) and the columns of \(A\) indexed by \(\phi, \varphi \subseteq S_n\), and \(\phi \subseteq S_n\). The principal submatrices of \(A\) are denoted by \(A^\phi\), where \(\phi \subseteq S_n\).

**Partial Permutations**

A partial permutation of \(S_n\) is a bijection, \(\sigma\), of a subset of \(S_n\) onto itself. The domain of \(\sigma\) is denoted by \(\text{dom}(\sigma)\), and the cardinality of \(\sigma\) is denoted by \(|\sigma|\). A complete permutation is defined as a partial permutation \(\sigma\) with \(\text{dom}(\sigma) = S_n\). The completion of a partial permutation, denoted as \(\hat{\sigma}\), is defined by:

\[
\hat{\sigma} = \begin{cases} 
\sigma(i) & \text{if } i \in \text{dom}(\sigma) \\
i & \text{if } i \in S_n \setminus \text{dom}(\sigma) 
\end{cases}
\] (206)

We use the conventional definition of the signature of a permutation:

\[
\text{sgn}(\sigma) = \begin{cases} 
-1 & \text{if } \sigma \text{ is an odd permutation} \\
1 & \text{if } \sigma \text{ is an even permutation} 
\end{cases}
\] (207)

The signature of a partial permutation, denoted as \(\text{sig}(\sigma)\), is defined by:

\[
\text{sig}(\sigma) = (-1)^{\hat{\sigma}} \text{sgn}(\sigma)
\] (208)

where \(\text{sgn}(\sigma)\) is the conventional signature of \(\hat{\sigma}\).

Every partial permutation has a unique representation as a set of disjoint cycles. For example:

\(\sigma = \begin{pmatrix} 2 & 4 \\ 4 & 2 \end{pmatrix}\), we have cycle representation \(\{(2,4)\}\).

\(\hat{\sigma} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & \cdots & n \\ 1 & 4 & 3 & 2 & 5 & \cdots & n \end{pmatrix}\), which has cycle representation \(\{(1)(2,4)(3)(5)\ldots(n)\} = \{(2,4)\}\).

For the permutation \(\sigma = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}\), the cycle representation is \(\{(1)(2,3)\} = \{(2,3)\}\).

This shows that the parity of \(\sigma\) is the same as the parity of \(\hat{\sigma}\), i.e. \(\text{sgn}(\hat{\sigma}) = \text{sgn}(\sigma)\).
The unique partial permutation of degree zero has the empty set as its cycle representation. Here we define $\text{sig}(\sigma)=1$.

If $\sigma$ is a cyclic partial permutation of degree $k$, then $\text{sig}(\sigma)=(-1)^k(-1)^{k-1} = -1$. It follows that for any partial permutation, $\sigma$, $\text{sig}(\sigma)=(-1)^r$, where $r$ is the number of cycles appearing in the cycle representation of $\sigma$.

If $\sigma$ is a partial permutation, then the weight of $\sigma$ is defined as: $\omega(\sigma) = \bigoplus_{i\in \text{dom}(\sigma)} a_{i,\sigma(i)}$.

**Definition 8.65.** Define the following multisets:

(a) $\sigma_0^0 = \{1\}$  \quad $\sigma_0^1 = \emptyset$  \quad $\sigma_1^1 = \emptyset$

(b) $\sigma_k^0 = \{\omega(\sigma) \mid \sigma \in C_k^n \text{ and } \text{sgn}(\sigma) = \text{even} \}$  \quad $\forall k = 1, \ldots, n$

(c) $\sigma_k^1 = \{\omega(\sigma) \mid \sigma \in C_k^n \text{ and } \text{sgn}(\sigma) = \text{odd} \}$  \quad $\forall k = 2, \ldots, n$

Define the following two formal polynomials, where each element of the sequence is viewed as a multiset.

$$p_A^+(\lambda) = \bigoplus_{q=0}^n \left( \sigma_q^{\text{par}(q)} \otimes \lambda^{n-q} \right) = \left( \sigma_n^{\text{par}(n)}, \sigma_{n-1}^{\text{par}(n-1)}, \ldots, \sigma_1^1, \sigma_0^0 \right) \quad (209)$$

$$p_A^-(\lambda) = \bigoplus_{q=0}^n \left( \sigma_q^{\text{par}(q+1)} \otimes \lambda^{n-q} \right) = \left( \sigma_n^{\text{par}(n+1)}, \sigma_{n-1}^{\text{par}(n)}, \ldots, \sigma_1^1, \sigma_0^1 \right) \quad (210)$$

By definition, we have $\sigma_1^1 = \emptyset$, $\sigma_0^0 = \{1\}$, and $\sigma_0^1 = \emptyset$.

Since “$\otimes$” is replaced by “$\bigoplus$” from the set $S$, then we will drop “$\otimes$”, and simply write “$\bigoplus$” instead.

Or we may simply drop the symbol altogether and assume the proper multiplication symbol.

**Example 8.66.** Consider the matrix $A = \begin{bmatrix} \{1\} & \{2\} & \{3\} \\ \{4\} & \{7\} & \{9\} \\ \{5\} & \{1\} & \{3\} \end{bmatrix}$, with $\oplus \equiv \text{“}\otimes\text{”}$, and $\otimes \equiv \oplus^{\text{n,n}}$ \hfill \[\Box\]

We have $\sigma_0^0 = \{1\}$, $\sigma_0^1 = \emptyset$,

$\sigma_1^1 = \{1,3,7\}$, $\sigma_0^1 = \emptyset$,

$\sigma_2^0 = \{3,7,21\}$, $\sigma_2^0 = \{8,9,15\}$,

$\sigma_3^0 = \{12,21,90\}$, $\sigma_3^0 = \{9,24,105\}$

$$p_A^+(\lambda) = \{1\} \otimes \lambda^3 \oplus \emptyset \otimes \lambda^2 \oplus \{3,7,21\} \otimes \lambda \oplus \{9,24,105\} = \{1\} \lambda^3 \oplus \{3,7,21\} \lambda \oplus \{9,24,105\}$$

and

$$p_A^-(\lambda) = \emptyset \otimes \lambda^3 \oplus \{1,3,7\} \otimes \lambda^2 \oplus \{8,9,15\} \otimes \lambda \oplus \{12,21,90\} = \{1,3,7\} \lambda^2 \oplus \{8,9,15\} \lambda \oplus \{12,21,90\}$$

To define an evaluation map, we make the following definitions:
\[ p_\lambda^+(a) = \bigoplus_{q=0}^{n-1} \left( \sigma^{\text{par}(q)}_q \otimes \{a\}^{n-q} \right) \quad \text{and} \quad p_\lambda^-(a) = \bigoplus_{q=0}^{n-1} \left( \sigma^{\text{par}(q+1)}_q \otimes \{a\}^{n-q} \right) \] (211)

If \( A_{n \times n} \in S_{n \times n} \) is a matrix, then
\[ p_\lambda^+(A) = \bigoplus_{q=0}^{n-1} \left( \sigma^{\text{par}(q)}_q \otimes A^{n-q} \right) \quad \text{and} \quad p_\lambda^-(A) = \bigoplus_{q=0}^{n-1} \left( \sigma^{\text{par}(q+1)}_q \otimes A^{n-q} \right) \] (212)

We note here that each evaluation in Equation (212) is a matrix a set in each entry.
\[ [p_\lambda^+(A)]_{ij} = \bigoplus_{q=0}^{n-1} \left( \sigma^{\text{par}(q)}_q \otimes [A^{n-q}]_{ij} \right) \quad \text{and} \quad [p_\lambda^-(A)]_{ij} = \bigoplus_{q=0}^{n-1} \left( \sigma^{\text{par}(q+1)}_q \otimes [A^{n-q}]_{ij} \right) \] (213)

**Example 8.67.** Consider the matrix in Example (8.66) along with \( p_\lambda^+(\lambda) \) and \( p_\lambda^-(\lambda) \).

1. Calculate \( p_\lambda^+(\{7\}) \) and \( p_\lambda^-(\{7\}) \).
   \[
p_\lambda^+(\{7\}) = \{1\} \otimes \{7\} \uplus \{3, 7, 21\} \otimes \{7\} \uplus \{9, 24, 105\} = \{343\} \uplus \{21, 49, 147\} \uplus \{9, 24, 105\} = \{9, 21, 24, 49, 105, 147, 343\}
   \]
   \[
p_\lambda^-(\{7\}) = \{1, 3, 7\} \otimes \{7\} \uplus \{8, 9, 15\} \otimes \{7\} \uplus \{12, 21, 90\} = \{49, 147, 343\} \uplus \{56, 63, 105\} \uplus \{12, 21, 90\} = \{12, 21, 49, 56, 63, 90, 105, 147, 343\}
   \]

2. Calculate \( p_\lambda^+(A) \) and \( p_\lambda^-(A) \).

\[
A^2 =
\begin{bmatrix}
\{1, 8, 15\} & \{2, 3, 14\} & \{3, 9, 18\} \\
\{4, 28, 45\} & \{8, 9, 49\} & \{12, 27, 63\} \\
\{4, 5, 15\} & \{3, 7, 10\} & \{9, 9, 15\}
\end{bmatrix}
\]

\[
A^3 =
\begin{bmatrix}
\{1, 8, 15\} & \{2, 3, 14\} & \{3, 9, 18\} \\
\{8, 56, 90\} & \{16, 18, 98\} & \{24, 54, 126\} \\
\{12, 15, 45\} & \{9, 21, 30\} & \{27, 27, 45\}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\{4, 32, 60\} & \{8, 12, 56\} & \{12, 36, 72\} \\
\{28, 196, 315\} & \{56, 63, 343\} & \{84, 189, 441\} \\
\{36, 45, 135\} & \{27, 63, 90\} & \{81, 81, 135\}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\{5, 40, 75\} & \{10, 15, 70\} & \{15, 45, 90\} \\
\{4, 28, 45\} & \{8, 9, 49\} & \{12, 27, 63\} \\
\{12, 15, 45\} & \{9, 21, 30\} & \{27, 27, 45\}
\end{bmatrix}
\]

92
\[ p_{A}^{+}(A) = \{1 \otimes A \oplus \{3, 7, 21\} \otimes A \oplus \{9, 24, 105\} \otimes I \]

\[
\begin{bmatrix}
1 & 8 & 15 \\
8 & 56 & 90 \\
12 & 15 & 45 \\
3 & 7 & 21 \\
9 & 24 & 105 \\
\end{bmatrix}
\begin{bmatrix}
2 & 3 & 14 \\
16 & 18 & 98 \\
9 & 21 & 30 \\
6 & 14 & 42 \\
8 & 12 & 56 \\
\end{bmatrix}
\begin{bmatrix}
3 & 9 & 18 \\
24 & 54 & 126 \\
27 & 27 & 45 \\
27 & 27 & 63 \\
12 & 36 & 72 \\
84 & 189 & 441 \\
81 & 81 & 135 \\
27 & 63 & 189 \\
15 & 45 & 90 \\
12 & 27 & 63 \\
9 & 21 & 63 \\
9 & 24 & 105 \\
\end{bmatrix}
\]

\[ p_{A}^{-}(A) = \{1, 3, 7\} \otimes A^2 \oplus \{8, 9, 15\} \otimes A \oplus \{12, 21, 90\} \otimes I \]

\[
\begin{bmatrix}
1 & 8 & 15 \\
3 & 24 & 45 \\
7 & 56 & 105 \\
8 & 9 & 15 \\
12 & 21 & 90 \\
\end{bmatrix}
\begin{bmatrix}
2 & 3 & 14 \\
6 & 9 & 42 \\
14 & 21 & 98 \\
16 & 18 & 30 \\
8 & 9 & 49 \\
\end{bmatrix}
\begin{bmatrix}
3 & 9 & 18 \\
9 & 27 & 54 \\
21 & 63 & 126 \\
24 & 27 & 45 \\
12 & 27 & 63 \\
36 & 81 & 189 \\
84 & 189 & 441 \\
72 & 81 & 135 \\
9 & 9 & 15 \\
27 & 27 & 45 \\
63 & 63 & 105 \\
24 & 27 & 45 \\
12 & 21 & 90 \\
\end{bmatrix}
\]

Looking closely at the two matrices above, it may be noted that the two matrices have the same
elements in each mset in each element of the corresponding matrices. The following theorem shows that this is not a coincidence.

**Theorem 8.68.** \( p^+_A(A) = p^-_A(A) \), with the definitions of Equations (212).

**Proof.** The following proof is adapted from [30].

A path \( \pi \in \{1,2,\ldots,n\} \) is a sequence of pairs \( \{ (i_0, i_1), (i_1, i_2), \ldots, (i_{t-1}, i_t) \} \) where each \( i_k \) belongs to \( S_n \). The number \( t \) is called the length of \( \pi \) and is denoted by \( |\pi| \). The \( i_1 \)'s are called the vertices of \( \pi \) and the pairs \( (i_{k-1}, i_k) \) are the edges of \( \pi \). The vertex \( i_0 \), denoted \( \alpha(\pi) \), is the beginning of the path, and the vertex \( i_t \), denoted \( \beta(\pi) \), is the end of the path \( \pi \). The weight of the path \( \pi \), denoted \( \omega(\pi) \), is \( \omega(\pi) = \sum_{k=0}^{t-1} a_{i_k i_{k+1}} \). We make the convention that for each \( i \in S_n \), there is a unique (empty) path \( \pi_i \) such that \( |\pi_i| = 0, \alpha(\pi_i) = \beta(\pi_i) = i \), and \( \omega(\pi_i) = 1 \).

Let \( 1 \leq i_0 \leq n \) and let \( T^+_{ij} \) be the set of pairs \( (\sigma, \pi) \), where \( \sigma \) is a partial permutation and \( \pi \) is a path, which satisfy

\[
|\sigma| + |\pi| = n, \quad \alpha(\pi) = i, \quad \omega(\pi) = j, \quad \text{sig}(\sigma) = 1.
\]

The set \( T^-_{ij} \) is defined analogously as, except the conditions satisfied are

\[
|\sigma| + |\pi| = n, \quad \alpha(\pi) = i, \quad \omega(\pi) = j, \quad \text{sig}(\sigma) = -1.
\]

Denote \( T^+_{ij} \cup T^-_{ij} \) by \( T_{ij} \).

For \( k \geq 0 \),

\[
(A^k)_{ij} = \bigcup_{\{\sigma, \pi \in T^+_{ij} \}} \omega(\pi)
\]

\[
\begin{cases}
|\pi| = k \\
\alpha(\pi) = i \\
\beta(\pi) = j
\end{cases}
\]

(The convention regarding paths of length zero makes this formula valid for \( k=0 \) as well.) It follows that

\[
p^+_{ij} = \bigcup_{(\sigma, \pi) \in T^+_{ij}} \omega(\sigma) \square \omega(\pi) \quad p^-_{ij} = \bigcup_{(\sigma, \pi) \in T^-_{ij}} \omega(\sigma) \square \omega(\pi)
\]

The theorem asserts that these two sums are equal for all \( \{i, j\} \in S_n \). This follows from the following lemma. \( \square \)

**Lemma 8.69.** For each pair \( (i, j) \), with \( 1 \leq i, j \leq n \), there is a bijection \( \eta_{ij}: T^+_{ij} \to T^-_{ij} \) in such a way that \( \eta_{ij}(\sigma, \pi) = (\sigma', \pi') \) implies \( |\sigma| \cup |\pi| = |\sigma'| \cup |\pi'| \).

**Proof.** Represent each pair \( (\sigma, \pi) \in T_{ij} \) by a directed graph with vertices \( \{1,2,\ldots,n\} \), and two classes of edges:

\( U = \{ (i, \sigma(i)) \mid i \in \text{dom}(\sigma) \} \), and \( V = \{ (k, \ell) \mid (k, \ell) \text{ is an edge of } \pi \} \)

This graph will, in general, contain multiple edges, since \( \pi \) may traverse the same edges more than once, or the same edge may appear in both \( U \) and \( V \). \( \omega(\sigma) \omega(\pi) \) is the product, with multiplicities taken into account, of all the \( a_{k,\ell} \), where \( (k, \ell) \) is an edge of the graph associated to \( (\sigma, \pi) \).
Two examples are illustrated below (see Figure 4). Edges of $U$ are denoted by dashed lines, and the edges of $V$ are denoted by solid lines.

Consider the nodes $\{i_0, i_1, \ldots, i_q\}$. Then $\pi$ is a path (set of edges) connecting the nodes in that order — i.e. let $\pi = \{(i_0,i_1),\ldots,(i_{q-1},i_q)\}$. There is a smallest integer $v \geq 0$ such that either $i_v = i_v$ for some $u < v$ or $i_v \in \text{dom}(\sigma)$. So there exists a smallest integer $v$ such that either $i_v$ is repeated in $\pi$, or $i_v \in \text{dom}(\sigma)$. We let $v = \text{smallest}$ of the two cases if both exist. Indeed, if there is no pair of distinct indices $u$ and $v$ such that $i_u = i_v$, then $\pi$ has $|\pi| + 1$ distinct vertices; the edges $(i, \sigma(i))$ of $U$ account for $|\sigma|$ different vertices, and $|\sigma| + 1 = n + 1$, thus there must be a vertex of $\pi$ in $\text{dom}(\sigma)$. Furthermore, this smallest $v$ cannot have both properties, for if $i_v \in \text{dom}(\sigma)$ and $i_u = i_v$ for some $u < v$, then we have an index $u$ smaller than $v$ with $i_u \in \text{dom}(\sigma)$. In Figure 4(a), $v = 3$, since $i_0 = 1, i_1 = 2, i_2 = 4, i_3 = 2 = i_1$. In Figure 5(a) $v = 1$, since $i_0 = 1, i_1 = 2 \in \text{dom}(\sigma)$.

Case 1: If $i_u = i_v$ for $u < v$, then the loop $\{(i_u,i_{u+1}),\ldots,(i_{v-1},i_v)\}$ is removed from $\pi$ and adjoined as a new cycle to $\sigma$. (Observe that none of the vertices in this loop already belongs to $\text{dom}(\sigma)$.) In this instance we define $\eta_{ij}(\sigma,\pi) = (\sigma',\pi')$, where $\sigma'$ is the resulting longer partial permutation and $\pi'$ is the resulting shorter path. An example of this is given in Figure 4(a), with the result of applying $\eta_{ij}$ given in Figure 4(b). Here, $\eta_{ij}(\sigma,\pi) = (\sigma',\pi')$. In Figure 4(a), $\sigma = \begin{pmatrix} 3 & 6 \\ 6 & 3 \end{pmatrix}$, and $\pi = \{(1,2),(2,4),(4,2),(2,3)\}$, and in Figure 4(b), $\sigma' = \begin{pmatrix} 2 & 3 & 4 & 6 \\ 4 & 6 & 2 & 3 \end{pmatrix}$, and $\pi' = \{(1,2),(2,3)\}$.

Case 2: If $i_v \in \text{dom}(\sigma)$, then we define $\eta_{ij}(\sigma,\pi) = (\sigma',\pi')$ where $\sigma'$ is formed by removing the cycle containing $i_v$ from $\sigma$, and where $\pi'$ is formed by inserting this cycle into $\pi$. The results of applying $\eta_{ij}$ to the graph in Figure 5(a) is illustrated in Figure 5(b). In this example $\eta_{ij}(\sigma,\pi) = (\sigma',\pi')$, where: $\sigma = \begin{pmatrix} 2 & 4 & 5 & 6 \\ 4 & 5 & 2 & 6 \end{pmatrix}$, and $\pi = \{(1,2),(2,3)\}$, and in Figure 4(b), $\sigma' = \begin{pmatrix} 6 \\ 6 \end{pmatrix}$, and $\pi' = \{(1,2),(2,3),(2,4),(4,5),(5,2)\}$.

Since the number of cycles of $\sigma'$ differs by 1 from the number of cycles in $\sigma$, $\text{sig}(\sigma) = (\cdot)(\cdot) \cdot \text{sig}(\sigma')$, and thus $\eta_{ij}$ maps $T_{ij}^+$ into $T_{ij}^-$ and vice versa. It is easy to see that the composition $\eta_{ij} \circ \eta_{ij}$ is the identity map on $T_{ij}$, consequently the restriction of $\eta_{ij}$ to $T_{ij}^+$ is a bijection of $T_{ij}^+$ onto $T_{ij}^-$. 

![Graph with first property](image-url)
Finally, $\omega (\sigma \omega (\pi)) = \omega (\sigma \omega (\pi))$ — indeed, nothing has changed in the graph of $(\sigma, \pi)$ except the “colors” of the edges. The proof is complete. \hfill \Box
Applications

From the previous section we have the fact that, for a given matrix \( A \in \mathbb{S}_{n \times n} \), \( p^+_A(A) = p^-_A(A) \) using the definitions of Equations 212. This is a very strong result in that it is true for a general semiring. The list of applications can be seen for any set \( \mathbb{S} \), with two appropriate operations, which is a semiring, ring, or even a field.

Theorem 8.68 states that the two sides of the equation are matrices of msets, and the two matrices are identical. We can apply this theorem to the different algebra systems in which we have been working. Theorem 8.68 is a generalized version of the Cayley-Hamilton Theorem.

**Real Numbers System** In the Real number system we use \( \triangledown \equiv "+", \) and \( \circ \equiv "." \). Here, Theorem 8.68 becomes an alternative form of the Cayley-Hamilton Theorem.

**Example 8.70.** Consider the matrix 
\[
A = \begin{bmatrix}
1 & 2 & 3 \\
4 & 7 & 9 \\
5 & 1 & 3
\end{bmatrix}
\in \mathbb{R}_{n \times n}.
\]

In this example:
\[
p^+_A(A) = \{1\} \triangledown A^0 \triangledown \{3,7,21\} \triangledown A \triangledown \{9,24,105\} \triangledown I \\
p^-_A(A) = \{1,3,7\} \triangledown A^2 \triangledown \{8,9,15\} \triangledown A \triangledown \{12,21,90\} \triangledown I \\
\]

and it can be checked that each side of the equation is:
\[
\begin{bmatrix}
419 & 273 & 426 \\
975 & 1073 & 1410 \\
424 & 252 & 582
\end{bmatrix}
\]

Since this example is in the conventional algebra, with subtraction, the above equation becomes 
\( A^3 - 11A^2 - 1A + 15I = 0 \), which is the equation given by the ordinary Cayley-Hamilton Theorem.

**Max-Times Algebra** When Theorem 8.68 is applied to the Max-Times Algebra, we get an equation which is satisfied by the matrix. In \( \mathbb{M}^* \),

**Theorem 8.71 (Cayley Hamilton Theorem in Max-Times).**

In Max-Times, \( p^+_A(A) = p^-_A(A) \), where the equation \( p^+_A(x) = p^-_A(x) \) is given by definitions of Equations 212.

**Proof.** Use of Theorem 8.68 with \( \triangledown \equiv "\text{max}" \), and \( \circ \equiv "\times" \)

**Example 8.72.** Consider the matrix 
\[
A = \begin{bmatrix}
1 & 2 & 3 \\
4 & 7 & 9 \\
5 & 1 & 3
\end{bmatrix}
\in \mathbb{M}^*_{n \times n}.
\]

In this example:
\[
p^+_A(A) = \{1\} \triangledown A^0 \triangledown \{3,7,21\} \triangledown A \triangledown \{9,24,105\} \triangledown I \\
p^-_A(A) = \{1,3,7\} \triangledown A^2 \triangledown \{8,9,15\} \triangledown A \triangledown \{12,21,90\} \triangledown I
\]

97
\[ A^3 \oplus (21)A \oplus (105)\mathbf{I} = (7)A^2 \oplus (15)A \oplus (90)\mathbf{I} \]

For this example, it can be checked that each side of the above equation is:
\[
\begin{bmatrix}
105 & 98 & 126 \\
315 & 343 & 441 \\
105 & 70 & 105 \\
\end{bmatrix}
\]

This can be simplified to: \( A^3 \oplus 21A \oplus 105I = 7A^2 \).

**Max-Plus Algebra**  The Max-Plus Algebra was investigated in the first part of this thesis. We did not give a Characteristic Polynomial Equation for the Max-Plus Algebra system at that time, but now we have the tools to do so. Here we use \( \uplus \equiv \text{“max”} \), and \( \odot \equiv \text{“+”} \)

**Example 8.73.** Consider the matrix \( A = \begin{bmatrix}
1 & 2 & 3 \\
4 & 7 & 9 \\
5 & 1 & 3 \\
\end{bmatrix} \in M_{n \times n}^+ . \)

In this example:
\[
p^+_{\uplus}(A) = \{1\} \boxdot A^3 \uplus \{4, 8, 10\} \boxdot A \uplus \{9, 11, 15\} \boxdot I \\
p^-_{\uplus}(A) = \{1, 3, 7\} \boxdot A^2 \uplus \{6, 8, 10\} \boxdot A \uplus \{8, 11, 16\} \boxdot I \\
A^3 \oplus (10)A \oplus (15)I = (7)A^2 \oplus (10)A \oplus (16)I
\]

For this example, it can be checked that each side of the above equation is:
\[
\begin{bmatrix}
16 & 16 & 18 \\
21 & 21 & 23 \\
15 & 15 & 17 \\
\end{bmatrix}
\]

**Min-Times Algebra**  The Min-Times Algebra is another example of a Path Algebra. Here, we are able to give a Characteristic Polynomial Equation for this path algebra. Here, we use \( \uplus \equiv \text{“min”} \), and \( \odot \equiv \text{“*”} \), and the zero element is \( \infty \), and the multiplicative identity is 1.

**Example 8.74.** Consider the matrix \( A = \begin{bmatrix}
1 & 2 & 3 \\
4 & 7 & 9 \\
5 & 1 & 3 \\
\end{bmatrix} \).

In this example:
\[
p^+_{\uplus}(A) = \{1\} \boxdot A^3 \uplus \{4, 8, 10\} \boxdot A \uplus \{9, 11, 15\} \boxdot I \\
p^-_{\uplus}(A) = \{1, 3, 7\} \boxdot A^2 \uplus \{6, 8, 10\} \boxdot A \uplus \{8, 11, 16\} \boxdot I \\
A^3 \oplus (4)A \oplus (9)I = (1)A^2 \oplus (6)A \oplus (8)I
\]

For this example, it can be checked that each side of the above equation is:
\[
\begin{bmatrix}
3 & 0 & 0 \\
0 & 7 & 0 \\
0 & 0 & 7 \\
\end{bmatrix}
\]

**Minimal Equations in the Mset Algebra**

The natural question that arises is whether a minimal equation exists for matrices in the Mset algebra as they do for the conventional algebra.
Example 8.75. Consider the matrix: $A = \begin{bmatrix} 1 & 0 & b \\ 0 & 1 & c \\ 0 & 0 & 1 \end{bmatrix} \in \mathbb{R}$. 

Let $B = \varphi_+ (A) = \begin{bmatrix} \{1\} & \emptyset & \{b\} \\ \emptyset & \{1\} & \{c\} \\ \emptyset & \emptyset & \{1\} \end{bmatrix}$

Then $B^2 = \begin{bmatrix} \{1\} & \emptyset & \{b, b\} \\ \emptyset & \{1\} & \{c, c\} \\ \emptyset & \emptyset & \{1\} \end{bmatrix}$ and

$B^3 = \begin{bmatrix} \{1\} & \emptyset & \{b, b, b\} \\ \emptyset & \{1\} & \{c, c, c\} \\ \emptyset & \emptyset & \{1\} \end{bmatrix}$

The Characteristic Equation for $B$ is:

$$B^3 \uplus \{1,1,1\}B \uplus \emptyset I = \{1,1,1\}B^2 \uplus \emptyset B \uplus \{1\}I$$

which can be simplified to

$$B^3 \uplus \{1,1,1\}B = \{1,1,1\}B^2 \uplus \{1\}I$$

It can be seen that an equation of smaller degree exists, namely,

$$B^2 \uplus \{1\}I = \{1,1\}B$$

Is it possible to say that the minimal equation is a divisor of the characteristic equation?

Definition 8.76. We say that equation $p^+ = p^-$ divides equation $h^+ = h^-$ if there exists a polynomial $q^+ = q^-$ such that

$$h^+ = p^+q^+ \uplus p^-q^-$$

(217)

$$h^- = p^+q^- \uplus p^-q^+$$

(218)

Here, $p^+ = \{1\} B^2 \uplus \{1\} I$, and $p^- = \{1,1\} B$, and $h^+ = B^3 \uplus \{1,1,1\} B$, and $h^- = \{1,1,1\} B^2 \uplus \{1\} I$. For this example we note that if $q^+ = B$, and $q^- = I$, then

$$h^+ = B^3 \uplus \{1,1,1\}B = (\{1\} B^2 \uplus \{1\} I) \uplus (\{1\} B) \uplus (\{1\} I) = p^+q^+ \uplus p^-q^-$$

(219)

$$h^- = \{1,1,1\}B^2 \uplus \{1\}I = (\{1\} B^2 \uplus \{1\} I) \uplus (\{1\} I) \uplus (\{1\} B) \uplus (\{1\} I) = p^+q^- \uplus p^-q^+$$

(220)
If we apply $\varphi_\ast$ to Equation (214), we get

$$A^3 \oplus 3A = 3A^2 \oplus I$$

(221)

**Example 8.77.** Consider the matrix: $A = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} \in \mathbb{R}$. 

Let $E=\varphi_\ast (A) = \begin{bmatrix} \emptyset & \{1\} & \{1\} \\ \{1\} & \emptyset & \{1\} \\ \{1\} & \{1\} & \emptyset \end{bmatrix}$

Then $E^2 = \begin{bmatrix} \{1,1\} & \{1\} & \{1\} \\ \{1\} & \{1,1\} & \{1\} \\ \{1\} & \{1\} & \{1,1\} \end{bmatrix}$ and

$E^3 = \begin{bmatrix} \{1,1\} & \{1,1,1\} & \{1,1,1\} \\ \{1,1,1\} & \{1,1\} & \{1,1\} \\ \{1,1,1\} & \{1,1,1\} & \{1,1\} \end{bmatrix}$

The Characteristic Equation for $E$ is:

$$E^3 \uplus \emptyset E \uplus \emptyset I = \emptyset E^2 \uplus \{1,1\} E \uplus \{1,1\} I$$

(222)

which can be simplified to

$$E^3 = \{1,1,1\} E \uplus \{1,1\} I$$

(223)

It can be seen that an equation of smaller degree exists, namely,

$$E^2 = \{1\} E \uplus \{1,1\} I$$

(224)

It is noted that the minimal equation divides the characteristic polynomial is we let $q^+ = E \uplus I$, and $q^- = \emptyset$.

In this case we get:

$$h^+ = E^3 \uplus E^2$$

(225)

$$h^- = E^2 \uplus \{1,1\} E \uplus \{1\} E \uplus \{1,1\} I$$

(226)

We see that $h^+$, and $h^-$ have a common term of $E^2$, which can be removed to get the characteristic equation in Equation (223).
Example 8.78. Consider the matrix: \( A = \begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{bmatrix} \in \mathbb{R} \).

In the system \( \mathbb{R}_n \) we have that the characteristic equation is \( \Delta_A = \lambda^3 - 5\lambda^2 + 7\lambda - 3 \) and the minimal polynomial is \( \psi_A = \lambda^3 - 4\lambda + 3 \).

Now consider the same matrix \( B = \begin{bmatrix} \{2\} & \{1\} & \{1\} \\ \{1\} & \{2\} & \{1\} \\ \emptyset & \emptyset & \{1\} \end{bmatrix} \in \mathbb{R}^3 \).

The characteristic polynomial for \( B \) is \( \lambda^3 \uplus \{4, 2, 2\} \lambda \uplus \{1\} = \{2, 2, 1\} \lambda^2 \uplus \{1\} \lambda \uplus \{4\} \).

Looking for an annihilating polynomial of degree two, we consider the polynomial \( \alpha \lambda^2 \uplus \beta \lambda \uplus \gamma = \delta \lambda \uplus \varepsilon \). If we substitute \( B \) into the equation, we look for the msets that satisfy:

\[
\alpha B^2 \uplus \beta B \uplus \gamma = \delta B \uplus \varepsilon
\]  

(227)

\[
B^2 = \begin{bmatrix} \{4, 1\} & \{2, 2\} & \{1, 1, 2\} \\ \{2, 2\} & \{1, 4\} & \{1, 1, 2\} \\ \emptyset & \emptyset & \{1\} \end{bmatrix}.
\]

(1) (1,1)-element of (227) \( \implies \) \( \{\alpha, 4\alpha, 2\beta, 2\gamma\} = \{2\delta, \varepsilon\} \)

(2) (1,2)-element of (227) \( \implies \) \( \{2\alpha, 2\alpha, \beta\} = \{\delta\} \)

(3) (1,3)-element of (227) \( \implies \) \( \{\alpha, \alpha, 2\alpha, \beta\} = \{\delta\} \)

Examining the above statements, Equations (2) and (3), imply that \( \alpha = \emptyset \). So the only msets for the above polynomial are \( \alpha = \emptyset, \beta = \delta, \) and \( \gamma = \varepsilon \).

This example illustrates that a polynomial of degree smaller (than the characteristic polynomial) exists for the matrix \( A \) over \( \mathbb{R}_n \) but no polynomial of smaller degree exists for matrix \( B \) over \( \mathbb{R} \).

We will return to this example again in Example 8.91 to see why this occurs. \( \blacksquare \)

8.10 Linear Independence

Suppose we are given a set of vectors \( \underline{x}_1, \ldots, \underline{x}_n \), with elements in \( \mathbb{R}^n \). Under what conditions is this set of vectors linearly independent? Adapting the definition from linear algebra we would have the following definition.

Definition 8.79. The set of vectors \( \underline{x}_1, \ldots, \underline{x}_n \) is linearly independent if and only if

\[
c_1 \underline{x}_1 \uplus c_2 \underline{x}_2 \uplus \cdots \uplus c_n \underline{x}_n = d_1 \underline{x}_1 \uplus d_2 \underline{x}_2 \uplus \cdots \uplus d_n \underline{x}_n \implies c_i = d_i \ \forall \ i
\]  

(228)

101
A set of vectors is said to be **linearly dependent** if it is not linearly independent.

This definition is easily stated, but it is not easy, in practice, to show that a set is linearly independent.

### 8.11 Embeddings and Morphisms of Semirings

With the use of Propositions 7.1 and 7.2, we are able to conclude things about the semiring $S_1$, by considering the ring $R^D$. In particular any identity in $R^D$ which is wholly in $S_2$ can be carried over to $S_1$ by going, first, through the semiring $S$.

We will use the notation for a “positive” and “negative” determinant of a matrix.

**Definition 8.80.** If $A$ is a matrix then we define:

1. $|A|^+ = \sigma_n^+$
2. $|A|^− = \sigma_n^−$

**Proposition 8.81.** For the mapping $\varphi_2$ from $S$ to $S_1$, if $A \in S$, then

(a) $\varphi_2(A^\text{adj}^+) = (\varphi_2(A))^\text{adj}^+$

(b) $\varphi_2(|A|^+) = |\varphi_2(A)|^+$

(c) $\varphi_2(I) = I$

**Proof.** (a) and (b) follow from the fact that the epimorphism, $\varphi_2$, from $S$ to $S_2$ is applied to a matrix elementwise. So if $A = [a_{ij}]$, then $[\varphi_2(A)]_{ij} = [\varphi_2(a_{ij})]$. (c) is obvious since the epimorphism is applied elementwise.

**Example 8.82.** As an example of this relationship we will consider the identity in a ring: $|AB| = |A||B|$.

Since $R^D$ is such a ring, we write the identity in $R^D$ as:

$$|AB|^+ - |AB|^− = (|A|^+ - |A|^−)(|B|^+ - |B|^−)$$

(229)

This becomes:

$$|AB|^+ + |A|^+ |B|^− + |A|^− |B|^+ = |AB|^− + |A|^+ |B|^− + |A|^− |B|^−$$

(230)

which is an identity wholly in $S_2$, and therefore is true for all matrices over any semiring.

\[\blacksquare\]
Example 8.83. As another example we consider the ring identity:

\[ (\lambda I - A) \text{adj}(\lambda I - A) = \Delta_A I \]  \hspace{1cm} (231)

In a semiring, this becomes:

\[ \lambda I \text{adj}(\lambda I - A)^+ + A \text{adj}(\lambda I - A)^- + \Delta^- (\lambda) I \]
\[ = \lambda I \text{adj}(\lambda I - A)^- + A \text{adj}(\lambda I - A)^+ + \Delta^+ (\lambda) I \]  \hspace{1cm} (232)

Recall that:

Fact 8.84.

\[ \text{adj}(\lambda I - A) = \sum_{k=0}^{n-1} A_k \lambda^k \]  \hspace{1cm} (233)

where \( A_k = a_{k+1} I + a_{k+2} A + \cdots + a_n A^{n-(k+1)} \). The \( a_k \)'s are defined by:

\[ a_{k+1} = (-1)^{n-(k+1)} \sigma_{n-(k+1)} \], where the \( \sigma_k \)'s are the coefficients of the characteristic polynomial.

Example 8.85. We verify the identity of Example 8.83, in particular Equation (232).

Consider the matrix

\[
\begin{bmatrix}
1 & 2 & 1 \\
2 & 5 & 5 \\
3 & 10 & 16
\end{bmatrix}
\in \mathbb{R}^+.
\]

For this matrix, we have \( \Delta_A^+(\lambda) = \lambda^3 + 101\lambda + 129 \), and \( \Delta_A^- (\lambda) = 22\lambda^2 + 57\lambda + 130 \).

We have

\[
\begin{align*}
a_0^+ &= 129 & a_1^+ &= 101 & a_2^+ &= 0 & a_3^+ &= 1 \\
_a0^- &= 130 & a_1^- &= 57 & a_2^- &= 22 & a_3^- &= 0
\end{align*}
\]

\[
\begin{align*}
A_0^+ &= a_0^+ I + a_1^+ A + a_2^+ A^2 = \begin{bmatrix} 109 & 22 & 27 \\ 27 & 180 & 107 \\ 71 & 216 & 410 \end{bmatrix} & A_0^- &= a_0^- I + a_1^- A + a_2^- A^2 = \begin{bmatrix} 79 & 44 & 22 \\ 44 & 167 & 110 \\ 66 & 220 & 409 \end{bmatrix} \\
A_1^+ &= \begin{bmatrix} 1 & 2 & 1 \\ 2 & 5 & 5 \\ 3 & 10 & 16 \end{bmatrix} & A_1^- &= \begin{bmatrix} 22 & 0 & 0 \\ 0 & 22 & 0 \\ 0 & 0 & 22 \end{bmatrix} \\
A_2^+ &= I_{3 \times 3} & A_2^- &= 0_{3 \times 3}
\end{align*}
\]
\[
\text{adj}(\lambda I - A)^+ = A_0^+ + A_1^+ \lambda + A_2^+ \lambda^2 = \begin{bmatrix}
\lambda^2 + \lambda + 109 & 2\lambda + 22 & \lambda + 27 \\
2\lambda + 27 & \lambda^2 + 5\lambda + 180 & 5\lambda + 107 \\
3\lambda + 71 & 10\lambda + 216 & \lambda^2 + 16\lambda + 410
\end{bmatrix}
\]

\[
\text{adj}(\lambda I - A)^- = A_0^- + A_1^- \lambda + A_2^- \lambda^2 = \begin{bmatrix}
22\lambda + 79 & 44 & 22 \\
44 & 22\lambda + 167 & 110 \\
66 & 220 & 22\lambda + 409
\end{bmatrix}
\]

And it can be verified that Equation (232) holds, as each side of the equation is:

\[
\begin{bmatrix}
\lambda^3 + 23\lambda^2 + 188\lambda + 363 \\
2\lambda^2 + 71\lambda + 708 \\
3\lambda^2 + 137\lambda + 1733
\end{bmatrix}
\begin{bmatrix}
2\lambda^2 + 66\lambda + 598 \\
\lambda^2 + 27\lambda^2 + 347\lambda + 2153 \\
10\lambda^2 + 436\lambda + 5322
\end{bmatrix}
\begin{bmatrix}
\lambda^2 + 49\lambda + 651 \\
5\lambda^2 + 217\lambda + 2639 \\
\lambda^3 + 38\lambda^2 + 819\lambda + 7840
\end{bmatrix}
\]

\[\blacksquare\]

**Example 8.86.** As another example we consider the ring identity:

\[A_{k-1} - AA_k = a_k I\] (234)

This can written in a semiring as

\[A_{k-1}^+ + AA_k^- + a_k^- I = A_{k-1}^- + AA_k^+ + a_k^+ I\] (235)

\[\blacksquare\]

### 8.12 Ring of differences for the mset algebra over \( \mathbb{R}^+ \)

We may recall that the ring of differences is used to create the integers from the nonnegative integers. In this abstract algebra \((a, b)\) is the equivalence class associated with \(a - b\).

Let us consider the ring of differences created from \(3\mathbb{R}^+\). The equivalence relation for msets is \((\alpha_1, \alpha_2) \sim (\beta_1, \beta_2)\) if and only if \((\alpha_1 \oplus \beta_2) = (\alpha_2 \oplus \beta_1)\). As an example we may notice that \((\{2, 3\}, \{3, 4\}) \sim (\{1, 2\}, \{1, 4\})\). This has a very nice relation to the ring of differences created from the nonnegative integers. For the example above, if we apply the sum to each mset in the pairs, as in Definition (8.10), we get that \((5, 7) \sim (3, 5)\), which is the equivalence class for \(-2\) in the integers.

We may also notice that the equivalence class denoted by \((\{2, 3\}, \{3, 4\})\) can be written in an “easier” mset as \(\{2, 3, 3, 4\}\). In this manner we see that using the set \(\mathbb{R}^+\) as our underlying semiring, we can embed this semiring in the ring \(\mathbb{R}\).

With this method, we have:
**Note 8.87.** If \( \alpha, \beta \in \mathbb{R}^+ \), then the element \((\alpha, \beta) \in R^D\) over \( \mathbb{R}^+ \) can be written as \((\alpha \vee (-\beta)) \in \mathbb{R}^3\) as a convenience.

**Lemma 8.88.** The ring \( R^D \), for msets over \( \mathbb{R}^+ \), is an integral domain.

*Proof.* Suppose that \( (r, s) \otimes (r_1, s_1) = (0, 0) \). Then \((rr_1 + ss_1, rs_1 + sr_1) \sim (0,0)\). Therefore \( rr_1 + ss_1 = rs_1 + sr_1 \). From Lemma 8.27, we have that either (a) \( r=s \), or (b) \( r_1=s_1 \). In either case, we have that one of these two elements is equivalent to \((0,0)\).

The following lemma gives the invertible elements in \((\alpha, \beta) \in R^D\) over \( \mathbb{R}^+ \).

**Lemma 8.89.** If \((\alpha, \beta) (\gamma, \delta) \sim (\{1\}, \emptyset)\), with \( \alpha \cap \beta = \emptyset \), and \( \gamma \cap \delta = \emptyset \), then either:

1. \( \beta = \delta = \emptyset \), and \( |\alpha| = |\gamma| = 1 \), with \( \gamma_1 = \frac{1}{\alpha_1} \),
2. \( \alpha = \gamma = \emptyset \), and \( |\beta| = |\delta| = 1 \), with \( \delta_1 = \frac{1}{\beta_1} \).

*Proof.* Suppose \((\alpha, \beta) (\gamma, \delta) \sim (\{1\}, \emptyset)\), with \( \alpha \cap \beta = \emptyset \), and \( \gamma \cap \delta = \emptyset \).

Then

\[ \alpha \gamma \vee \beta \delta = \alpha \delta \vee \beta \gamma \vee \{1\}. \] (236)

We consider two cases for the proof.

(I.) One mset is not empty.

(a) \( \beta \neq \emptyset, \delta = \emptyset \)

(b) \( \beta = \emptyset, \delta \neq \emptyset \)

(c) \( \alpha \neq \emptyset, \gamma = \emptyset \)

(d) \( \alpha = \emptyset, \gamma \neq \emptyset \)

(II.) None of the msets are empty.

Let \( |\alpha| = a, |\beta| = b, |\gamma| = c, \) and \( |\delta| = d \).

(I.) The four subcases are all similar, so we will prove (I.a). Suppose that \( \beta \neq \emptyset \), and \( \delta = \emptyset \). Then Equation (236) becomes \( \alpha \gamma = \beta \gamma \vee \{1\} \). The consistency condition implies that \( ac = bc+1 \), or \( c(a-b)=1 \), since this condition is in the nonnegative integers then \( c=1 \) and \( a=b+1 \). The equation becomes

\[ \{a_1, a_2, \ldots, a_{k+1}\} \{c\} = \{b_1, b_2, \ldots, b_k\} \{c\} \vee \{1\} \]

which can be expanded as

\[ \{a_1c, a_2c, \ldots, a_{k+1}c\} = \{b_1c, b_2c, \ldots, b_kc, 1\} \]
Since these two sets are equal then either: (a) $a_1 c = 1$, or (b) $a_1 c = b_m c$ for some $m$. In the latter case we have that $a_1 = b_m$ which is a contradiction. In the former case, we use the same reasoning for $a_2 c$ to get a contradiction. Therefore case (I) cannot occur.

(II) Suppose that $\alpha \neq \emptyset$, $\beta \neq \emptyset$, $\gamma \neq \emptyset$, and $\delta \neq \emptyset$.

The consistency condition implies that

$$\begin{align*}
ac + bd &= ad + bc + 1 \\
(a - b)(c - d) &= 1
\end{align*}$$

Again, since we are working over the nonnegative integers, we have that $a-b=1$ and $c-d=1$, which implies that $a=b+1$, and $c=d+1$. We may also have that $b=a+1$, and $d=c+1$, but the proof of this case is similar. We suppose that all the elements are positive, and that they are in increasing (nondecreasing) order. So Equation (236) becomes:

$$\begin{align*}
\{a_1, a_2, \ldots, a_{k+1}\} \{c_1, c_2, \ldots, c_{m+1}\} \uplus \{b_1, b_2, \ldots, b_k\} \{d_1, d_2, \ldots, d_m\} \\
= \{a_1, a_2, \ldots, a_{k+1}\} \{d_1, d_2, \ldots, d_m\} \uplus \{b_1, b_2, \ldots, b_k\} \{c_1, c_2, \ldots, c_{m+1}\} \uplus \{1\}
\end{align*}$$

which is expanded to:

$$\begin{align*}
\{a_1 c_1, \ldots, a_1 c_{m+1}, \ldots, a_{k+1} c_1, \ldots, a_{k+1} c_{m+1}, b_1 d_1, \ldots, b_1 d_m, \ldots, b_k d_1, \ldots, b_k d_m\} \\
= \{a_1 d_1, \ldots, a_1 d_m, \ldots, a_{k+1} d_1, \ldots, a_{k+1} d_m, b_1 c_1, \ldots, b_1 c_{m+1}, \ldots, b_k c_1, \ldots, b_k c_{m+1}, 1\}
\end{align*}$$

(237)

Taking the maximum element of each side, we get that

$$\max\left(a_{k+1} c_{m+1}, b_k d_m\right) = \max\left(a_{k+1} d_m, b_k c_{m+1}, 1\right)$$

(238)

and comparing the minimum elements of each side gives:

$$\min\left(a_1 c_1, b_1 d_1\right) = \min\left(a_1 d_1, b_1 c_1, 1\right)$$

(239)

Equation (238) leads to either (a) $a_{k+1} c_{m+1} = 1$, or (b) $b_k d_m = 1$, for otherwise we get a contradiction of the empty “intersection” of pairwise sets. Similarly, if we compare the minimum elements of each set, we get either (1) $a_1 c_1 = 1$, or (2) $b_1 d_1 = 1$.

This leads to a combination of 4 separate cases.

1. $a_{k+1} c_{m+1} = 1$, and $a_1 c_1 = 1$.

2. $b_k d_m = 1$, and $b_1 d_1 = 1$. 

106
3. \( a_{k+1}c_{m+1} = 1 \), and \( b_1d_1 = 1 \).

4. \( b_kd_m = 1 \), and \( a_1c_1 = 1 \).

Cases (1) and (2) are similar as are cases (3) and (4). Each case leads to the same conclusion, so we will illustrate the procedure for cases (2) and (4). Consider case (2). Suppose \( b_kd_m = 1 \), and \( b_1d_1 = 1 \). We also know that \( b_kd_m \geq a_{k+1}c_{m+1} \), and \( a_1c_1 \geq b_1d_1 \). These statements lead to:

\[
1 = b_kd_m \geq a_{k+1}c_{m+1} \geq a_1c_1 \geq b_1d_1 \geq 1
\]  

(240)

Therefore all products in the above statement must equal 1. Therefore we have that \( a_i c_j = 1 \) for all \( i \) and \( j \), and \( b_id_j = 1 \) for all \( i \) and \( j \). Since we know that \( b_1 \leq b_k \leq \frac{1}{k} \), then \( \frac{1}{d_1} \geq \frac{1}{d_m} \geq 1 \), which implies that \( d_1 \geq d_m \geq 1 \). Since \( d_m \geq d_1 \) then \( d_1 = d_m \). Therefore \( d_1 = d_2 = \cdots = d_m \), and \( b_1 = b_2 = \cdots = b_k \).

For case (4), suppose \( b_kd_m = 1 \), and \( a_1c_1 = 1 \). We also know that \( b_kd_m \geq a_{k+1}d_{m+1} \), and \( b_1d_1 \geq a_1c_1 \). From these conditions, we get the following set of inequalities:

\[
1 = b_kd_m \geq a_{k+1}c_{m+1} \geq a_1c_1 = 1
\]  

(241)

\[
1 = b_kd_m \geq b_1d_1 \geq a_1c_1 = 1
\]  

(242)

Equations (241) and (242) imply that \( a_i c_j = 1 \) for all \( i \) and \( j \), and \( b_id_j = 1 \) for all \( i \) and \( j \). Equation (242) implies that \( b_1d_1 = 1 \), and this case becomes part of the previous case.

These cases show that every element on the LHS of Equation (237) must be “1”. Therefore every element on the RHS of Equation (237) must also be “1”. We also have that \( b_1 = b_2 = \cdots = b_k \), and \( d_1 = d_2 = \cdots = d_m \). Therefore we also have that \( a_1 = a_2 = \cdots = a_{k+1} \), and \( c_1 = c_2 = \cdots = c_{m+1} \).

The LHS of Equation (237) has two separate elements, say “ac” which occurs \((k+1)(m+1)\) times, and “bd” which occurs \((k)(d)\) times. Likewise the RHS of Equation (237) has “ad” which occurs \((k+1)(m)\) times, and “bc” which occurs \((k)(m+1)\) times, plus a separate “1”. Therefore either \( ac=ad \) which leads to a contradiction, or \( ac=bc \) which also leads to a contradiction.

Therefore case (II) is also impossible. The consistency condition implies the sizes of the msets for the result.

We revisit a past example, once again, to see how it can be worked with the ring of difference.

**Example 8.90.** Consider the matrix of Example (8.78): 
\[
A = \begin{bmatrix}
2 & 1 & 1 \\
1 & 2 & 1 \\
0 & 0 & 1
\end{bmatrix} \in \mathbb{R}^+.
\]

We translate this matrix into the Multiset Algebra: 
\[
B = \begin{bmatrix}
\{2\} & \{1\} & \{1\} \\
\{1\} & \{2\} & \{1\} \\
\emptyset & \emptyset & \{1\}
\end{bmatrix} \in 3^\mathbb{R}^+.
\]

107
We then translate this matrix into the Ring of Differences:

\[
E = \begin{bmatrix}
\{2\}, \emptyset & \{1\}, \emptyset & \{1\}, \emptyset \\
\{1\}, \emptyset & \{2\}, \emptyset & \{1\}, \emptyset \\
\emptyset, \emptyset & \emptyset, \emptyset & \{1\}, \emptyset
\end{bmatrix} \in R^D.
\]

We note that the Characteristic Polynomial for the matrix E is:

\[
(\{1\}, \emptyset)\lambda^3 \uplus (\emptyset, \{1, 2, 2\})\lambda^2 \uplus (\{2, 2, 4\}, \{1\})\lambda \uplus (\{1\}, \{4\})
\]  \hspace{1cm} (243)

It can be checked that

\[
(\{1\}, \emptyset)E^3 \uplus (\emptyset, \{1, 2, 2\})E^2 \uplus (\{2, 2, 4\}, \{1\})E \uplus (\{1\}, \{4\})I \equiv (\emptyset, \emptyset)
\]  \hspace{1cm} (244)

as the left side of Equation (244) is

\[
\begin{bmatrix}
\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 4 & 4 & 4 \end{bmatrix} & \begin{bmatrix} 1 & 2 & 2 \\ 2 & 4 & 4 \\ 8 & 8 & 8 \end{bmatrix} \\
\begin{bmatrix} 1 & 2 & 2 \\ 2 & 4 & 4 \\ 8 & 8 & 8 \end{bmatrix} & \begin{bmatrix} 1 & 2 & 2 \\ 4 & 4 & 4 \\ 8 & 8 & 8 \end{bmatrix}
\end{bmatrix}
\]  \hspace{1cm} (245)

\textbf{Example 8.91.} Once again we consider Example 8.78 and the matrix \( A \in \mathbb{R}^{+} \): \( A = \begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{bmatrix} \)

We convert this matrix to \( 3^{\mathbb{R}^{+}} \) as:

\( \hat{A} = \begin{bmatrix} \{2\} & \{1\} & \{1\} \\ \{1\} & \{2\} & \{1\} \\ \emptyset & \emptyset & \{1\} \end{bmatrix} \)

Then we convert this matrix to the ring of differences, \( R^D \):

\( \hat{A} = \begin{bmatrix} \{2\}, \emptyset & \{1\}, \emptyset & \{1\}, \emptyset \\ \{1\}, \emptyset & \{2\}, \emptyset & \{1\}, \emptyset \\ \emptyset, \emptyset & \emptyset, \emptyset & \{1\}, \emptyset \end{bmatrix} \)

The Characteristic Polynomial for \( A \) is \( \lambda^3 - 5\lambda^2 + 7\lambda - 3 = (\lambda - 1)^2(\lambda - 3) \).

The Minimal Polynomial for \( A \) is \( \lambda^2 - 4\lambda + 3 = (\lambda - 1)(\lambda - 3) \).

In \( 3^{\mathbb{R}^{+}} \), the Characteristic Equation is \( \lambda^3 \uplus \{2, 2, 4\} \lambda \uplus \{1\} = \{1, 2, 2\} \lambda^2 \uplus \{1\} \lambda \uplus \{4\} \).

In \( R^D \) the characteristic equation is: \( \{1\}, \emptyset)\lambda^3 + (\emptyset, \{1, 2, 2\})\lambda^2 + (\{2, 2, 4\}, \{1\})\lambda + (\{1\}, \{4\}) \).

Is there a division algorithm for the polynomials over \( R^D \)? Given \( p(\lambda) \), and \( h(\lambda) \), can \( q(\lambda) \) and \( r(\lambda) \) be found such that \( h(\lambda) = q(\lambda) p(\lambda) + r(\lambda) \), with \( \partial(r) < \partial(p) \)? In order to have a division algorithm we must have the leading coefficient of \( p(\lambda) \) to be an invertible element. As we have seen
this is the case if the polynomial is monic, where we define a monic polynomial in $R^D$ as a polynomial with leading coefficient equal to ($\{1\}, \emptyset$).

We note that ($\{1\}, \emptyset$) is a “root” of the Characteristic Polynomial. We divide by $\lambda-\{(1), \emptyset\} = \lambda+\{(\emptyset,\{1\})$}

$$
\lambda^2 + (\emptyset,\{2,2\})\lambda + ((4),\{1\})
\frac{\lambda + (\emptyset,\{1\})\lambda^3 + (\emptyset,\{1,2,2\})\lambda^2 + ([2,2,4],\{1\})\lambda + ([1,4])}{\lambda^3 + (\emptyset,\{1\})\lambda^2}
\frac{(\emptyset,\{2,2\})\lambda^2 + ([2,2,4],\{1\})\lambda}{((4),\{1\})\lambda + ((1),\{4\})}
\frac{((4),\{1\})\lambda + ((1),\{4\})}{(\emptyset,\emptyset)}
$$

(246)

So, we have:

$$(\emptyset,\emptyset)\lambda^3 + (\emptyset,\{1,2,2\})\lambda^2 + ([2,2,4],\{1\})\lambda + ([1,4])$$

$$= \left(\lambda - \{(1), \emptyset\}\right) \left(\lambda^2 + (\emptyset,\{2,2\})\lambda + ((4),\{1\})\right)$$

(247)

We also note that ($\{2\},\{1\}$) is a “root”.

$$
\lambda + (\{1\},\{2\})\lambda^2 + (\emptyset,\{2,2\})\lambda + ((4),\{1\})
\frac{\lambda + ([1],\{2\})\lambda^2 + ([2,2],\{1\})\lambda}{\lambda^3 + ([1],\{2\})\lambda^2 + ([4],\{1\})}
\frac{([4],\{1\})\lambda + ([1],\{4\})}{(\emptyset,\emptyset)}
$$

(248)

The Characteristic Polynomial becomes:

$$
(\{1\},\emptyset)\lambda^3 + (\emptyset,\{1,2,2\})\lambda^2 + ([2,2,4],\{1\})\lambda + ([1,4])
$$

$$= \left(\lambda - ([1],\emptyset)\right) \left(\lambda - ([2],\{1\})\right) \left(\lambda - ([1,2],\emptyset)\right)$$

(249)

We notice that the Characteristic Polynomial factors into linear factors. Since the three factors are distinct the minimal polynomial is the same as the characteristic polynomial.

The roots of the Characteristic Polynomial are eigenvalues of the given matrix. Below we list the eigenvectors for the matrix $B$ above.
(A) \((\{1,2\}, \emptyset)\) is an eigenvalue.

\[
\mathcal{A} - (\{1,2\}, \emptyset)I = \mathcal{A} + (\emptyset, \{1,2\})I
\]

\[
= \begin{bmatrix}
(\{2\}, \{1,2\}) & (\{1\}, \emptyset) & (\{1\}, \emptyset) \\
(\{1\}, \emptyset) & (\{2\}, \{1,2\}) & (\{1\}, \emptyset) \\
(\emptyset, \emptyset) & (\emptyset, \emptyset) & (\{1\}, \{1,2\})
\end{bmatrix}
\]

Letting \( \mathbf{z} = \begin{bmatrix} (x_1, x_2) \\
(y_1, y_2) \\
(z_1, z_2) \end{bmatrix} \), and setting \((\mathcal{A} - \lambda I) \mathbf{z} = \mathbf{0}\) yields the three equations:

1. \((x_2, x_1) + (y_1, y_2) + (z_1, z_2) \sim (\emptyset, \emptyset) \iff (x_2 + y_1 + z_1, x_1 + y_2 + z_2) \sim (\emptyset, \emptyset)\)
2. \((x_1, x_2) + (y_2, y_1) + (z_1, z_2) \sim (\emptyset, \emptyset) \iff (x_1 + y_2 + z_1, x_2 + y_1 + z_2) \sim (\emptyset, \emptyset)\)
3. \((2z_2, 2z_1) \sim (\emptyset, \emptyset)\)

These equations lead to the eigenvector \(\begin{bmatrix} (\{1\}, \emptyset) \\
(\{1\}, \emptyset) \\
(\emptyset, \emptyset) \end{bmatrix}\).

It can be checked that \(\mathcal{A} \begin{bmatrix} (\{1\}, \emptyset) \\
(\{1\}, \emptyset) \\
(\emptyset, \emptyset) \end{bmatrix} = \begin{bmatrix} (\{1\}, \emptyset) \\
(\{1\}, \emptyset) \\
(\emptyset, \emptyset) \end{bmatrix} = \begin{bmatrix} (\{1\}, \emptyset) \\
(\{1\}, \emptyset) \\
(\emptyset, \emptyset) \end{bmatrix} \).

(B) \((\{1\}, \emptyset)\) is an eigenvalue.

The corresponding eigenvector is: \(\begin{bmatrix} (\{1\}, \emptyset) \\
(\{1\}, \emptyset) \\
(\emptyset, \{2\}) \end{bmatrix}\).

(C) \((\{2\}, \{1\})\) is an eigenvalue.

The corresponding eigenvector is: \(\begin{bmatrix} (\{1\}, \emptyset) \\
(\emptyset, \{1\}) \\
(\emptyset, \emptyset) \end{bmatrix}\).

So, although in \(\mathbb{R}\) the characteristic equation for \(A\) is \(\Delta(\lambda) = (\lambda - 1)^2(\lambda - 3)\), and the minimal polynomial for \(A\) is \(\psi(\lambda) = (\lambda - 1)(\lambda - 3)\), we see that the “1” which is a repeated root in \(\mathbb{R}\) has become two different elements in \(\mathbb{R}^D\), namely \((\{1\}, \emptyset)\), and \((\{2\}, \{1\})\).
It may be noticed that
\[ \sum \lambda_i = (\{1\}, \emptyset) + (\{2\}, \{1\}) + (\{1, 2\}, \emptyset) = (\{1, 2, 2\}, \emptyset) = \text{Trace}(\mathcal{A}) \] (250)
and
\[ \prod \lambda_i = (\{1\}, \emptyset) (\{2\}, \{1\}) (\{1, 2\}, \emptyset) = (\{4\}, \{1\}) = (-1)^3|\mathcal{A}| \] (251)
As we see from the above example, the roots of the characteristic equation are eigenvalues of the given matrix. The following theorem shows that this is true for the case in which the ring of differences is an integral domain, as is the case for the ring of differences, \( R^D \), for \( \mathbb{R}^+ \).
The following lemma is from [25, page 161].

**Lemma 8.92.** A matrix, \( A \), over a ring \( R_{n \times n} \) is a divisor of zero in \( R_{n \times n} \) if and only if \( |A| \) is a divisor of zero in \( R \).

With this lemma, we may now prove

**Lemma 8.93.** If \( R^D \) is an integral domain, then \( Ax=0 \) has nonzero solutions if and only if \( |A| \neq 0 \).

**Proof.** Suppose that \( Ax=0 \) has a nonzero solution. Let \( X=[x_1 \cdots x_k] \in R_{n \times n} \). Then \( A \) is a divisor of zero. Therefore by Lemma 8.92, \( |A| \) is a divisor of zero. If \( |A| \) is a divisor of zero then there exists an element, \( d \), such that \( |A| \cdot d = 0 \). Since \( R^D \) is an integral domain then \( |A| = 0 \).

Conversely, suppose that \( |A| = 0 \). Then there exists a nonzero matrix \( X \) such that \( AX=0 \). Let \( x \) equal one of the nonzero columns of \( X \). Then \( Ax=0 \), with \( x \neq 0 \).

\[ \square \]

Now we can prove

**Theorem 8.94.** An eigenvalue of \( A \) is a root of the Characteristic Polynomial of \( A \), and every root of the Characteristic Polynomial is an eigenvalue of \( A \).

**Proof.** Suppose that \( Ax=\lambda x \) has a nonzero solution \( x \) (an eigenvector).

\[ Ax = \lambda x \]
\[ \iff (\lambda I - A)x = 0 \]
\[ \iff |\lambda I - A| = 0 \]
\[ \iff \Delta_A(\lambda) = 0 \]

\[ \square \]

We note that \( (\{1, 2\}, \emptyset) \) is the “largest” “positive” eigenvalue, and the eigenvector corresponding to this eigenvalue is strictly “nonnegative.” Can we say that the maximum “nonnegative” eigenvalue is the only eigenvalue with a strictly nonnegative eigenvector?

111
8.13 Application.

We include the following example to show how the mset algebra may be used to solve a problem from the Max-Plus Algebra system. The following problem is from [24], where the system of equations is solved using the symmetrized algebra. The mset algebra offers an alternative method of solution.

Example 8.95. Find the solutions of:
\[
\begin{align*}
\max(x, y - 4, 1) &= \max(x - 1, y + 1, 2) \\
\max(x + 3, y + 2, -5) &= \max(y + 2, 7)
\end{align*}
\]
This can be written in matrix form as:
\[
\begin{bmatrix}
0 & -4 \\
3 & 2
\end{bmatrix} \otimes \begin{bmatrix}
x \\
y
\end{bmatrix} + \begin{bmatrix}
1 \\
-5
\end{bmatrix} = \begin{bmatrix}
-1 & 1 \\
-\infty & 2
\end{bmatrix} \otimes \begin{bmatrix}
x \\
y
\end{bmatrix} + \begin{bmatrix}
2 \\
7
\end{bmatrix}
\]
(253)

To solve this system of equations, we first translate the problem to the Max-Times algebra to get:
\[
\begin{bmatrix}
e^0 & e^{-4} \\
e^3 & e^2
\end{bmatrix} \otimes \begin{bmatrix}
e^x \\
e^y
\end{bmatrix} + \begin{bmatrix}
e^1 \\
e^{-5}
\end{bmatrix} = \begin{bmatrix}
e^{-1} & e^1 \\
e^0 & e^2
\end{bmatrix} \otimes \begin{bmatrix}
e^x \\
e^y
\end{bmatrix} + \begin{bmatrix}
e^2 \\
e^7
\end{bmatrix}
\]
(254)

This equation is translated into the mset algebra using \(\mathbb{R}\) as the set \(\mathbb{S}\). We then translate the system into an equation of the form \(Ax=b\):
\[
\begin{bmatrix}
1, -e^{-1} \\
ea^3 \\
e^2, -e^{-2}
\end{bmatrix} \otimes \begin{bmatrix}
e^x \\
e^y
\end{bmatrix} = \begin{bmatrix}
e^2, -e^{-1} \\
e^7, -e^{-5}
\end{bmatrix}
\]
(255)

We now apply Cramer’s Rule to this matrix equation. We use the equation 186 from Note 8.49.

\[
\begin{align*}
\{e^2, -e^2, -e^1, e^1\}e^x \uplus \{e^3, -e^{-9}, -e^9, e^{-9}\} &= \{e^{-1}, -e^{-1}\}e^y \uplus \{e^4, -e^4, -e^3, e^3\} \\
\{e^2, -e^2, -e^1, e^1\}e^y \uplus \{e^5, -e^4\} &= \{e^{-1}, -e^{-4}\}e^x \uplus \{e^7, -e^{-5}, -e^6, e^{-6}\}
\end{align*}
\]
(256, 257)

or
\[
\begin{align*}
\{e^2e^x, -e^2e^x, -e^1e^x, e^1e^x, e^3, -e^{-9}, -e^9, e^{-9}\} &= \{e^{-1}e^x, -e^4e^x, e^4, -e^{-4}, -e^3, e^3\} \\
\{e^2e^y, -e^2e^y, -e^1e^y, e^1e^y, e^5, -e^4\} &= \{e^{-1}e^y, -e^4e^y, e^7, -e^{-5}, -e^6, e^{-6}\}
\end{align*}
\]
(258, 259)

We translate back to \(\mathbb{R}^+\), by moving all negative terms to the other side of the equation:
\[
\begin{align*}
\{e^2e^x, e^1e^x, e^4e^x, e^3, e^4, e^3, e^3, e^{-9}\} &= \{e^{-1}e^x, e^2e^x, e^1e^x, e^4, e^3, e^3, e^{-9}\} \\
\{e^2e^y, e^1e^y, e^4e^y, e^5, e^{-5}, e^6\} &= \{e^{-1}e^y, e^2e^y, e^1e^y, e^7, e^{-6}, e^4\}
\end{align*}
\]
(260, 261)

Translating back to Max-Times algebra by applying “max” to each mset, we get:
\[
\begin{align*}
e^4e^x \uplus e^4 &= e^2e^2 \uplus e^8 \implies e^4e^x = e^8 \implies e^x = e^4 \\
e^4e^y \uplus e^6 &= e^2e^y \uplus e^7 \implies e^4e^y = e^7 \implies e^y = e^3
\end{align*}
\]
(262, 263)
And, finally translating back into the Max-Plus Algebra, we get:

\[
  \begin{align*}
  x &= 4 \\
  y &= 3
  \end{align*}
\]

### 8.14 Cramer’s Rule

We have seen, in the previous sections, that Cramer’s Rule is a viable method for working with systems of equations over msets. In this section we will further refine the methods used previously. As we examine Example (8.95) closely, we see that we have taken the algebra system \( S_{n \times n} \) and imbedded it into a system \( S_{n \times n}^* \), which has negatives. In this example, where we use \( \mathbb{R}^+ \) and \( \mathbb{R} \), it seems natural to use negative signs, but in a general semiring, we may use an “\( \ominus \)” instead. By imbedding the semiring \( S_{n \times n} \) in \( S_{n \times n}^* \), the notation becomes somewhat easier to use. Most of the results of this section could be modified to include only \( S_{n \times n} \).

We begin with some of the results of [27], after some the definitions of the notation used in this section.

**Definition 8.96 (Determinants).** For a matrix \( A \in \mathbb{R}^{n \times n} \), we define

\[
(1) \quad |A|^+ = \bigoplus_{\sigma \text{ even}} \left( \bigotimes_{1 \leq i \leq n} A_{i\sigma(i)} \right)
\]

\[
(2) \quad |A|^− = \bigoplus_{\sigma \text{ odd}} \left( \bigotimes_{1 \leq i \leq n} A_{i\sigma(i)} \right)
\]

**Definition 8.97.** If \( A \) is a square matrix, then the minor, \( M_{ij} \), of the element \( a_{ij} \) is the determinant of the matrix obtained by deleting the \( i \)th row and \( j \)th column of \( A \).

Recall that, as in \( \mathbb{R} \), the sign pattern for cofactors is:

\[
\begin{vmatrix}
  + & - & + & \cdots \\
  - & + & - & \cdots \\
  + & - & + & \cdots \\
  \vdots & \vdots & \vdots & \ddots
\end{vmatrix}
\]

(264)

We now define the “positive adjoint matrix” and “negative adjoint matrix” by:

**Definition 8.98 (Adjoint Matrix).** Let \( A \in S_{n \times n} \), then

\[
(1) \quad A^{\text{adj}+} = \begin{bmatrix}
  M_{11}^+ & M_{21}^+ & M_{31}^+ & \cdots \\
  M_{12}^+ & M_{22}^+ & M_{32}^+ & \cdots \\
  M_{13}^+ & M_{23}^+ & M_{33}^+ & \cdots \\
  \vdots & \vdots & \vdots & \ddots
\end{bmatrix}
\]

113
(2) $A^{\text{adj}} = \begin{bmatrix} M_{11}^- & M_{12}^+ & M_{13}^- & \cdots \\ M_{21}^+ & M_{22}^- & M_{23}^+ & \cdots \\ M_{31}^- & M_{32}^+ & M_{33}^- & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}$

**Fact 8.99.** If $A, B \in \mathbb{S}^S$, and $A = B$, then $|A|^+ = |B|^+$, and $|A|^+ = |B|^-$.

The following condition holds for some semirings. We have seen in Lemma 8.27 that this condition holds for multisets over the nonnegative numbers.

**Definition 8.100 (Switching Condition).**
In semiring $\mathbb{S}$, if $\alpha u \oplus \beta v = \beta u \oplus \alpha v$, then $\alpha = \beta$, or $u = v$.

We can now consider Cramer’s Rule in its entirety.

**Theorem 8.101 (Cramer’s Rule).** Let $\mathbb{S}$ be a semiring and suppose $A \in \mathbb{S}_{n \times n}$. If $\underline{z}$ satisfies the system of equations

$$AZ = b$$

then $\underline{z}$ satisfies the Cramer’s Rule equations stated as:

$$|A|^+\underline{z} + A^{\text{adj}-}\underline{b} = |A|^{-}\underline{z} + A^{\text{adj}+}\underline{b}$$

(66)

If, in addition, $\mathbb{S}$ is a cancellative semiring in which the switching condition holds then if $\underline{z}$ satisfies Equation (66) then either:

1. $|A|^+ = |A|^{-}$, or
2. $A\underline{z} = \underline{b}$

**Proof.** We prove this for the first element, $x_1$. The proofs for the other variables are similar.

Suppose $\underline{z}$ is a solution to $AZ = \underline{b}$ and consider the matrix equation:

$$\begin{bmatrix} a_1 & a_2 & \cdots & a_n \end{bmatrix} \begin{bmatrix} x_1e_1 & e_2 & \cdots & e_n \end{bmatrix} = \begin{bmatrix} b & a_2 & \cdots & a_n \end{bmatrix}$$

(67)

We write this equation as:

$$AX_1 = B_1$$

(68)

Take the determinant of each side of Equation (68). Use Equation (230), and note that $|X_1|^+ = x_1$, and $|X_1|^+ = 0$, to get

$$|AX_1|^+ + |A|^+x_1 = |AX_1|^+ + |A|^+x_1$$

(69)
Using Fact 8.99, we see that $|AX_1|^+ = |B_1|^+$, and $|AX_1|^− = |B_1|^−$.  
So Equation (269) becomes

$$|A|^+x_1 + |B_1|^− = |A|^−x_1 + |B_1|^+$$

(270)

Finally we claim that $|B_1|^+ = (A^{\text{adj}} + \underline{\frac{1}{2}})$, and $|B_1|^− = (A^{\text{adj}} - \underline{\frac{1}{2}})$. To show that this is true, we have:

$$|B_1| = \begin{bmatrix} b & a_2 & \cdots & a_n \end{bmatrix}$ = \sum_{i=1}^{n} b_i A_{i1} = \sum_{i=1}^{n} b_i (-1)^{i+1} M_{i1}$$

(271)

So,

$$|B_1|^+ - |B_1|^− = \sum_{i=1}^{n} (-1)^{i+1} b_i M_{i1}$$

$$= b_1 M_{11} - b_2 M_{21} + b_3 M_{31} - \cdots$$

$$= b_1 (M_{11}^+ - M_{11}^−) - b_2 (M_{21}^+ - M_{21}^−) + b_3 (M_{31}^+ - M_{31}^−) - \cdots$$

(272)

So Equation (270) can be written as Equation (266) for the variable $x_1$. The other variables are proved analogously. We have shown that if $\underline{\frac{1}{2}}$ is a solution to Equation (265) then $\underline{\frac{1}{2}}$ is also a solution to Equation (266).

We would like to be able to start with a solution to Equation (266) and show that this is a solution to the system given by Equation (265). In order to obtain this result, we must assume that the semiring $S$ is cancellative and also that the Switching condition holds in $S$.

Equation (266) is equivalent to

$$\sum_{j} a_{ij} (|A|^+ \underline{\frac{1}{2}} + A^{\text{adj}} - \underline{\frac{1}{2}}) = \sum_{j} a_{ij} (|A|^− \underline{\frac{1}{2}} + A^{\text{adj}} + \underline{\frac{1}{2}})$$

(273)

as we simply multiply by $a_{ij}$ and sum.

We will need the ring identity

$$\sum_{j} a_{ij} |B_j| = |A|b_i$$

(274)

which can be rewritten in the semiring as

$$\sum_{j} a_{ij} |B_j|^+ + b_i |A|^− = \sum_{j} a_{ij} |B_j|^− + b_i |A|^+$$

(275)

We notice that the expansion of Equation (273) has terms similar to Equation (275), except it is missing a term on each side; so we add the corresponding sides of the equation (identity)

$$b_i (|A|^+ + |A|^−) = b_i (|A|^+ + |A|^−)$$

to Equation (273) to get

115
\[
\sum_j a_{ij}|A|^+ x_j + \sum_j a_{ij}|B_j|^+ + b_i|A|^+] + b_i|A|^{-}
= \sum_j a_{ij}|A|^{-} x_j + \sum_j a_{ij}|B_j|^+ + b_i|A|^+] + b_i|A|^{-}.
\]

Using the identity from Equation (275) yields the equation

\[
\sum_j a_{ij}|A|^+ x_j + b_i|A|^{-} = \sum_j a_{ij}|A|^{-} x_j + b_i|A|^+.
\] (277)

which can be written as

\[
\sum_j a_{ij}|A|^+ x_j + b_i|A|^{-} = \sum_j a_{ij}|A|^{-} x_j + b_i|A|^+.
\] (278)

and Equation (278) is equivalent to

\[
|A|^+(Ax) + |A|^{-}b = |A|^{-}(Ax) + |A|^+b
\] (279)

The switching condition implies that either

(1) \(|A|^+ = |A|^{-}\), or

(2) \(Ax = b\)

\[\square\]

**Note 8.102.** In a general semiring, it is possible to have a solution to the Cramer’s Rule equations in Equation (266) that is not satisfied by the corresponding system since \(ψ_2\) is an epimorphism from \(S\) to \(S_1\).

The following is an example of the above note.

**Example 8.103.** Let \(S = (\mathbb{R}, \cup, \cap)\) be the semiring of sets using “union” as the sum, and “intersection” as the product. Consider the system:

\[
\begin{bmatrix}
  a & c \\
  b & d
\end{bmatrix}
\begin{bmatrix}
  x \\
  y
\end{bmatrix}
= \begin{bmatrix}
  e \\
  f
\end{bmatrix}
\] (280)

This equation has the corresponding Cramer’s Rule equations:

\[
(a \cap d \cap x) \cup (f \cap c) = (b \cap e \cap x) \cup (e \cap d)
\] (281)

\[
(a \cap d \cap y) \cup (b \cap e) = (b \cap e \cap y) \cup (a \cap f)
\] (282)
Consider the sets:

\[
\begin{align*}
a &= \{1, 2\} & b &= \{0, 1\} \\
c &= \{3, 5\} & d &= \{2, 3\} \\
e &= \{3, 5\} & f &= \{3, 4\} \\
x &= \{2, 4\} & y &= \{3, 4\}
\end{align*}
\] (283)

It can be seen that the sets given in Equation (283) make Equations (281) and (282) true, yet they do not satisfy Equation (280).

We include, here, an example which illustrates how we can use the adjoint matrix to solve a system of linear equations in the (Max, $\times$)-algebra system.

**Example 8.104.** In the Max-Times algebra system, solve the system:

\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\begin{bmatrix}
x \\
y
\end{bmatrix}
\begin{bmatrix}
16 \\
3
\end{bmatrix} =
\begin{bmatrix}
5 & 4 \\
3 & 1
\end{bmatrix}
\begin{bmatrix}
x \\
y
\end{bmatrix}
\begin{bmatrix}
2 \\
16
\end{bmatrix}
\] (284)

We translate this problem into the mset algebra, and imbedding the system $\mathbb{R}^+$ into $\mathbb{R}$

\[
\begin{bmatrix}
\{1, -5\} & \{2, -4\} \\
\{3, -3\} & \{4, -1\}
\end{bmatrix}
\begin{bmatrix}
x \\
y
\end{bmatrix} =
\begin{bmatrix}
\{2, -16\} \\
\{16, -3\}
\end{bmatrix}
\] (285)

We then form the following four quantities:

1. $|A|^+ = \{1, -5\} \{4, -1\} = \{-20, -1, 4, 5\}$
2. $|A|^− = \{3, -3\} \{2, -4\} = \{-12, -6, 6, 12\}$
3. $A^\text{adj}^+ = \begin{bmatrix}
\{4, -1\} & \varnothing \\
\varnothing & \{1, -5\}
\end{bmatrix}
\begin{bmatrix}
\{2, -16\} \\
\{16, -3\}
\end{bmatrix} =
\begin{bmatrix}
\{-64, -2, 8, 16\} \\
\{-80, -3, 15, 16\}
\end{bmatrix}$
4. $A^\text{adj}^- = \begin{bmatrix}
\varnothing & \{2, -4\} \\
\{3, -3\} & \varnothing
\end{bmatrix}
\begin{bmatrix}
\{2, -16\} \\
\{16, -3\}
\end{bmatrix} =
\begin{bmatrix}
\{-64, -6, 12, 32\} \\
\{-48, -6, 6, 48\}
\end{bmatrix}$

Using Equation (266) we get

\[
\begin{bmatrix}
\{-20, -2, 4, 5\} \\
\{-48, -6, 6, 48\}
\end{bmatrix} \uplus
\begin{bmatrix}
\{-64, -6, 12, 32\} \\
\{-48, -6, 6, 48\}
\end{bmatrix} =
\begin{bmatrix}
\{-12, -6, 6, 12\} \\
\{-48, -6, 6, 48\}
\end{bmatrix} \uplus
\begin{bmatrix}
\{-64, -2, 8, 16\} \\
\{-80, -3, 15, 16\}
\end{bmatrix}
\] (286)

After moving “negative” terms to the opposite side of the equation, we get the following equation with all terms positive:
\[
\{4,5,6,12\} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 2,12,32,64 \\ 3,6,48,80 \end{bmatrix} = \begin{bmatrix} 1,6,12,20 \end{bmatrix} \uplus \begin{bmatrix} 6,8,16,64 \end{bmatrix} = \begin{bmatrix} 6,15,16,48 \end{bmatrix}
\] (287)

If we now translate back into the \(\mathfrak{M}^*\)-system, we get:

\[
12 \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 64 \\ 80 \end{bmatrix} = 20 \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 64 \\ 48 \end{bmatrix}
\] (288)

And each of these equations contain one variable, for which we can solve.

\[
12x \uplus 64 = 20x \uplus 64 \\
64 = 20x \uplus 64 \\
x \leq \frac{16}{5}
\]

\[
12y \uplus 80 = 20y \uplus 48 \\
80 = 20y \\
y = 4
\]

So, the solutions to the original system of equations is:

\[
\begin{bmatrix} x \leq 3.2 \\ y = 4 \end{bmatrix}
\] (289)

We include, here, a list of the cases that can occur in the \(\mathfrak{M}^*\) algebra.

**Proposition 8.105 \(\mathfrak{M}^*\).** If \(Ax=b\) is a system of equations over the Max-Times algebra then the Cramer’s Rule equations are

\[
|A|^+ \begin{bmatrix} a \\ b \end{bmatrix} \uplus A^{\text{adj}} \begin{bmatrix} a \\ b \end{bmatrix} = |A|^- \begin{bmatrix} a \\ b \end{bmatrix} \uplus A^{\text{adj}} \begin{bmatrix} a \\ b \end{bmatrix}
\] (266)

For each variable, we arrive at an equation of the form

\[
ax_i \uplus b_i = cx_i \uplus d_i.
\] (290)

The solution to this equation leads to nine cases, which can be considered independently:

1. \(a > c, b_i > d_i\)
2. \(a > c, b_i < d_i\)
3. \(a > c, b_i = d_i\)
4. \(a < c, b_i > d_i\)
5. \(a < c, b_i < d_i\)
6. \(a < c, b_i = d_i\)
7. \(a = c, b_i > d_i\)
8. \(a = c, b_i < d_i\)
9. \(a = c, b_i = d_i\)

Cases (4)-(6) need not be considered as they are symmetric to cases (1)-(3).

For each of these cases, we analyze the solution to Equation (290).
(1) Equation (290) has no solution for \( x_i \).

(2) \( x_i = \frac{d_i}{a} \)

(3) \( x_i \leq \frac{d_i}{a} \)

(7) \( x_i \geq \frac{b_i}{c} \)

(8) \( x_i \geq \frac{d_i}{a} \)

(9) In this case there are infinitely many solutions. \( x_i \) becomes an arbitrary variable. Use ratios to find solutions.

We include, here, an example for which case (9), above, occurs and in which case we get a parameter of solutions.

**Example 8.106.** In the Max-Times algebra system, solve the system:

\[
\begin{bmatrix} 2 & 3 \\ 4 & 5 \end{bmatrix} \otimes \begin{bmatrix} x \\ y \end{bmatrix} \oplus \begin{bmatrix} 3 \\ 2 \end{bmatrix} = \begin{bmatrix} 4 & 3 \\ 1 & 5 \end{bmatrix} \otimes \begin{bmatrix} x \\ y \end{bmatrix} \oplus \begin{bmatrix} 2 \\ 7 \end{bmatrix}
\]

(291)

We translate this problem into the mset algebra, and imbedding the system \( \mathbb{R}^+ \) into \( \mathbb{R} \)

\[
\begin{bmatrix} \{2, -4\} & \{3, -3\} \\ \{4, -1\} & \{5, -5\} \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \begin{bmatrix} \{2, -3\} \\ \{7, -2\} \end{bmatrix}
\]

(292)

We then form the following four quantities:

(1) \( |A|^+ = \{-20, -10, 10, 20\} \)

(2) \( |A|^-= \{-12, -3, 3, 12\} \)

(3) \( A^\text{adj}+ = \begin{bmatrix} 5, -5 \\ \emptyset & \{2, -4\} \end{bmatrix} \begin{bmatrix} \{2, -3\} \\ \{7, -2\} \end{bmatrix} = \begin{bmatrix} \{-15, -10, 10, 15\} \\ \{-28, -4, 8, 14\} \end{bmatrix} \)

(4) \( A^\text{adj}- = \begin{bmatrix} \emptyset & \{3, -3\} \\ \{4, -1\} & \emptyset \end{bmatrix} \begin{bmatrix} \{2, -3\} \\ \{7, -2\} \end{bmatrix} = \begin{bmatrix} \{-21, -6, 6, 21\} \\ \{-12, -2, 3, 8\} \end{bmatrix} \)

Using Equation (266) we get

\[
\{ -20, -10, 10, 20 \} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \{ -21, -6, 6, 21 \} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \{ -12, -3, 3, 12 \} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \{ -15, -10, 10, 15\} \begin{bmatrix} x \\ y \end{bmatrix}
\]

(293)

After moving “negative” terms to the opposite side of the equation, we get the following equation with all terms positive:
\[
\{3,10,12,20\} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 6,10,15,21 \end{bmatrix} \mid \begin{bmatrix} 3,10,12,20 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 6,10,15,21 \end{bmatrix} = \{3,10,12,20\} \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 6,10,15,21 \end{bmatrix} \]
\tag{294}
\]

If we now translate back into the \( \mathfrak{M}^* \)-system, we get:

\[
20 \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 21 \\ 28 \end{bmatrix} = 20 \begin{bmatrix} x \\ y \end{bmatrix} \uplus \begin{bmatrix} 21 \\ 14 \end{bmatrix} \]
\tag{295}
\]

And each of these equations contain one variable, for which we can solve.

\[
20y \uplus 28 = 20y \uplus 14 \\
20y \uplus 28 = 20y \\
y \geq \frac{7}{5} = 1.4 \\
20x \uplus 21 = 20x \uplus 21 \\
x \geq \frac{21}{20}, \text{ and use ratios}
\]

The equation for “x” implies there are infinitely many solutions, so we use ratios to determine the relationship between the variables.

\[
\left( x = \frac{21}{20} \text{ and } y = \frac{7}{5} \right) \implies \left( x = \frac{3}{4}y \right)
\]

So, the solutions to the original system of equations is:

\[
\begin{aligned}
y \geq 1.4 \text{ and } \\
x = \frac{3}{4}y
\end{aligned}
\]
\tag{296}

\[\blacksquare\]

8.15 A Connection between \( \mathfrak{M}^* \) and \( \mathbb{R}^+ \).

In this section we attempt to show a connection between the two different algebras: \( \mathfrak{M}^* \) and \( \mathbb{R}^+ \). This connection can be used to find the eigenvalue/eigenvectors of a matrix when considered as a matrix over either \( \mathbb{R}^+ \) or \( \mathfrak{M}^* \). Msets plays the crucial role of connecting these two different algebras.

The goal is to find an eigenvalue/eigenvector equation over msets which contains the information for both the \( \mathfrak{M}^* \)-algebra, and \( \mathbb{R} \)-algebra.
Preliminaries  We begin our discussion with a few definitions. First is the concept of a mset
norm. I will use the notation “‖·‖” for the norm. For the present discussion this norm will
represent either the usual max-norm, ‖·‖, sometimes called the infinity norm, and the “1-norm”,
‖·‖1.
If α is an mset then we define:

\[
‖α‖ = \begin{cases} 
‖α‖_\infty = \max_i (α_i) & \text{if } α \in \mathbb{R}^n \\
‖α‖_1 = \sum_i (α_i) & \text{if } α \in \mathbb{R}^+ 
\end{cases}
\]  (297)

Let us verify that both norms are multiplicative and additive.

Lemma 8.107. ‖·‖ is multiplicative and additive for the two norms of this section. In particular,

(a) ‖·‖∞ is multiplicative over \(\mathbb{R}^n\).

(b) ‖·‖∞ is additive over \(\mathbb{R}^n\).

(c) ‖·‖1 is multiplicative over \(\mathbb{R}\).

(d) ‖·‖1 is additive over \(\mathbb{R}\).

Proof.

(a)

\[
‖α \oplus β‖ = ‖α \oplus β‖_\infty \\
= \max (α \oplus β) \\
= \max (\max_{i} (α_i) , \max_{j} (β_j)) \\
= \max (‖α‖_\infty , ‖β‖_\infty ) \\
= ‖α‖ \oplus ‖β‖
\]  (298)

(b)

\[
‖α \otimes β‖ = ‖α \otimes β‖_\infty \\
= \max_{i,j} (α_i \cdot β_j) \\
= \max (α_i) \cdot \max (β_j) \\
= ‖α‖_\infty \cdot ‖β‖_\infty \\
= ‖α‖ \otimes ‖β‖
\]  (299)
(c) 
\[ ||\alpha \uplus \beta|| = ||\alpha \uplus \beta||_1 \]
\[ = \sum_k (\alpha \uplus \beta) \]
\[ = \sum_i (\alpha_i) + \sum_j (\beta_j) \]
\[ = ||\alpha||_1 + ||\beta||_1 = ||\alpha|| + ||\beta|| \]

(d) 
\[ ||\alpha \otimes \beta|| = ||\alpha \otimes \beta||_1 \]
\[ = \sum_{i,j} (\alpha_i \beta_j) \]
\[ = \sum_i (\alpha_i) \cdot \sum_j (\beta_j) \]
\[ = ||\alpha||_1 \cdot ||\beta||_1 \]
\[ = ||\alpha|| \otimes ||\beta|| \]

\[ \square \]

**Definition 8.108.** If \( \mathbf{z} \) is a vector with msets as elements then 
\[ n(\mathbf{z}) = \begin{bmatrix} ||x_1|| \\ ||x_2|| \\ \vdots \\ ||x_n|| \end{bmatrix}, \]

**The Connection** The following theorem is important in that it allows us to find some of the necessary requirements for an irreducible mset matrix to possess an eigenvalue/eigenvector equation.

**Theorem 8.109.** If \( \mathbf{A} \) is an irreducible mset matrix and \( \mathbf{A}_\mathbf{z} = \lambda \mathbf{z} \), then 
\[ ||\lambda||n(\mathbf{z}) = n(\mathbf{A})n(\mathbf{z}). \]

**Proof.** Suppose \( \mathbf{A} \) is an irreducible mset matrix, and \( \mathbf{A}_\mathbf{z} = \lambda \mathbf{z} \) is an mset eigenvalue equation. Then, for each \( i \),
\[ \lambda x_i = \sum_{k=1}^n a_{ik} \otimes x_k \]  
(302)

We consider two cases:

(Case 1) For \( \mathbb{R} \), we apply the “1-norm” to each side of Equation (302).
\[ \|\lambda z\| = \|\lambda\| \|x_i\| \]
\[ = \| \sum_{k=1}^{n} a_{ik} x_k \| \]
\[ = \sum_{k=1}^{n} \|a_{ik} x_k\| \]
\[ = \sum_{k=1}^{n} \|a_{ik}\| \cdot \|x_k\| \]
\[ = \sum_{k=1}^{n} (\alpha(n) y_k) (u(n) y_k) \]
\[ = \sum_{k=1}^{n} (\alpha(n) y_k) (u(n) y_k) \]
\[ \] Therefore, Equation (302) becomes
\[ \|\lambda\| n(z) = \alpha(n) u(n) \]

(Case II) For \( \mathbb{R}^* \), we apply the “\( \infty \)-norm” to each side of Equation (302):
\[ \|\lambda z\|_{\infty} = \max\{\lambda \otimes x_i\} \]
\[ = \max\{\lambda\} \cdot \max\{x_i\} \]
\[ = \max\{\lambda\} \cdot \max\{x_k\} \]
\[ = \max_{k} \{ \max\{a_{ik}\} \cdot \max\{x_k\} \} \]
\[ = \max \|a_{ik}\| \cdot \|x_k\| \]
Therefore, Equation (302) becomes:
\[ \|\lambda\|_{\infty} n(z) = \alpha(n) u(n) \]

So Equation (302) is true for both cases.

\[ \Box \]

**Corollary 8.110.** If \( A \) is an irreducible mset matrix and \( Ax = \lambda x \), with \( z \geq 0 \), then
(a) \( \|\lambda\|_{\infty} = \nu(n(A)) \)
(b) \( \|\lambda\|_{1} = \rho(n(A)) \)

**Proof.** We shall assume that \( \nu(z) > 0 \), since otherwise we could multiply by \( (I \otimes A)^{-1} > 0 \).
Equation (304) is a matrix equation in \( \mathbb{R}^* \), while Equation (306) is a matrix equation in \( \mathbb{R}^* \). In each case \( \nu(\lambda) \geq 0 \) and irreducible, and \( \nu(z) > 0 \). In \( \mathbb{R}^* \), we know that \( \rho \) is eigenvalue of \( \nu(A) \). For \( \mathbb{R}^* \), we know that \( \nu(A) \) is the unique eigenvalue of \( \nu(A) \). In either case the result follows.

\[ \Box \]

**Corollary 8.111.** If \( A \) is an irreducible matrix over \( \mathbb{R}^+ \), or \( \mathbb{R}^* \), and \( Ax = \lambda x \), with \( z \geq 0 \), then
(a) \( \| \lambda \|_\infty = \nu(A) \)

(b) \( \| \lambda \|_1 = \rho(A) \)

**Proof.** If \( A \) is a matrix in \( \mathbb{M}^* \) or \( \mathbb{R} \), then the mset matrix associated with \( A \) has a one-element mset in each entry. So \( n(A) = A \), and the result follows.

\[
\begin{pmatrix} 6 & 1 \\ 4 & 6 \end{pmatrix}
\]

\text{as a matrix in either} \( \mathbb{M}^* \) or \( \mathbb{R} \). The mset eigenvalue equation is

\[
\begin{bmatrix} \{6\} & \{1\} \\ \{4\} & \{6\} \end{bmatrix} \boxtimes \begin{bmatrix} \{1\} \\ \{2\} \end{bmatrix} = \{6,2\} \boxtimes \begin{bmatrix} \{1\} \\ \{2\} \end{bmatrix}
\]

\[\text{(307)}\]

In \( \mathbb{R} \), we get the conventional eigenvalue equation

\[
\begin{bmatrix} 6 & 1 \\ 4 & 6 \end{bmatrix} \cdot \begin{bmatrix} 1 \\ 2 \end{bmatrix} = 8 \cdot \begin{bmatrix} 1 \\ 2 \end{bmatrix}
\]

\[\text{(308)}\]

And, in \( \mathbb{M}^* \), we get the eigenvalue equation

\[
\begin{bmatrix} 6 & 1 \\ 4 & 6 \end{bmatrix} \otimes \begin{bmatrix} 1 \\ 2 \end{bmatrix} = 6 \otimes \begin{bmatrix} 1 \\ 2 \end{bmatrix}
\]

\[\text{(309)}\]

Corollary 8.111 gives the fact that if a matrix has an eigenvalue equation over the mset algebra, then we can apply \( \| \cdot \|_1 \) to get the Real eigenvalue equation, and we can apply \( \| \cdot \|_\infty \) to get the Max-Times equation. Although the theory is nice, the caveat is that a general mset matrix – even one with only one element in each mset – may not have an mset eigenvalue equation. The following example illustrates this fact.

**Example 8.113.** Consider the matrix

\[
A = \begin{bmatrix} 4 & 2 & 1 \\ 2 & 7 & 2 \\ 1 & 2 & 4 \end{bmatrix}
\]

as a matrix in either \( \mathbb{M}^* \) or \( \mathbb{R} \).

Then \( \rho(A) = 9 \), and \( \nu(A) = 7 \).

Therefore the mset eigenvalue equation for \( A \) must be:

\[
\begin{bmatrix} \{4\} & \{2\} & \{1\} \\ \{2\} & \{7\} & \{2\} \\ \{1\} & \{2\} & \{4\} \end{bmatrix} \boxtimes \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \{7, \lambda_2, \lambda_3\} \boxtimes \begin{bmatrix} x \\ y \\ z \end{bmatrix}
\]

\[\text{(310)}\]

where \( x, y, z \) are msets, and \( \lambda_2 + \lambda_3 = 2 \) and \( 7 \geq \lambda_2 \geq \lambda_3 \).
If one of $x, y$, or $z$ equals $\emptyset$, then all sets must equal $\emptyset$. Hence all three elements must be nonempty. So $|\lambda| = 3$.

This leads to the following equations:

\[
4x \uplus 2y \cup z = \{7, \lambda_2, \lambda_3\}x \\
2x \uplus 7y \cup 2z = \{7, \lambda_2, \lambda_3\}y \\
x \uplus 2y \cup 4z = \{7, \lambda_2, \lambda_3\}z
\]

Equation (312) is simplified as

\[
2x \uplus 2z = \{\lambda_2, \lambda_3\}y \\
4x \uplus 4z = 2\{\lambda_2, \lambda_3\}y \\
x \uplus z = \frac{1}{2}\{\lambda_2, \lambda_3\}y
\]

If we add the LHS and RHS of Equations (311) and (313), and replace $(x \uplus z)$ by Equation (316), and replace $(4x \uplus 4y)$ by Equation (315), then we get:

\[
\left\{ \frac{\lambda_2}{2}, \frac{\lambda_3}{2}, 2, 2, 2\lambda_2, 2\lambda_3 \right\} y = \frac{1}{2}\{7\lambda_2, 7\lambda_3, \lambda_2^2, \lambda_3^2, \lambda_2\lambda_3, \lambda_2\lambda_3\} y
\]

If $y=\emptyset$ then $x=z=\emptyset$, which can not occur in an eigenvalue equation. Therefore $y \neq \emptyset$.

Equation (317) becomes:

\[
\{\lambda_2, \lambda_3, 4, 4, 4\lambda_2, 4\lambda_3\} = \{7\lambda_2, 7\lambda_3, \lambda_2^2, \lambda_3^2, \lambda_2\lambda_3, \lambda_2\lambda_3\}
\]

It can be shown that there is no $\lambda_2$ and $\lambda_3$ that will satisfy Equation (318).

Therefore the matrix $A$ has no mset eigenvalue equation.

\[
\begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{bmatrix}
\]

\textbf{Example 8.114.} We return once more the Example 8.78. $A=$

The eigenvalue equation for matrix $A$ is:

\[
\left[ \begin{array}{ccc} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{array} \right] \left[ \begin{array}{c} \{2\} \\ \{1\} \\ \emptyset \end{array} \right] = \left[ \begin{array}{c} \{1\} \\ \{1\} \\ \emptyset \end{array} \right]
\]

This mset eigenvalue equation will collapse to either the Real eigenvalue equation or to the Max-eigenvalue equation, depending upon which norm is used.

The question of which matrices possess an mset eigenvalue equation remains open. It will most likely involve higher combinatorics.

We will classify the simple $2 \times 2$ matrices which possess an eigenvalue equation.
Theorem 8.115. If $A$ is a $2 \times 2$ matrix with one element in each mset, then $A$ has an mset eigenvalue equation if and only if

1. $A$ is a diagonal matrix.
2. $A$ is reducible.
3. $A$ is singular.
4. $A$ has the form $\begin{bmatrix} \{a\} & \{c\} \\ \{b\} & \{a\} \end{bmatrix}$

Proof. Assume that $a \geq d$ in the proofs.

1. $\begin{bmatrix} \{a\} & \emptyset \\ \emptyset & \{d\} \end{bmatrix} \boxtimes \begin{bmatrix} \{1\} \\ \{1\} \end{bmatrix} = \{a\} \boxtimes \begin{bmatrix} \emptyset \\ \emptyset \end{bmatrix}$

2. $\begin{bmatrix} \{a\} & \{c\} \\ \emptyset & \{d\} \end{bmatrix} \boxtimes \begin{bmatrix} \{1\} \\ \{1\} \end{bmatrix} = \{a\} \boxtimes \begin{bmatrix} \emptyset \\ \emptyset \end{bmatrix}$

3. $\begin{bmatrix} \{a\} & \{c\} \\ \{ka\} & \{kc\} \end{bmatrix} \boxtimes \begin{bmatrix} \{1\} \\ \{1\} \end{bmatrix} = \{a,ck\} \boxtimes \begin{bmatrix} \{1\} \\ \{1\} \end{bmatrix}$

The proof of part (3) is sufficient for any rank one matrix as $\begin{bmatrix} \{1\} \\ \{k\} \end{bmatrix} \boxtimes \begin{bmatrix} \{a\} & \{c\} \\ \{ka\} & \{kc\} \end{bmatrix} \boxtimes \begin{bmatrix} \{1\} \\ \{1\} \end{bmatrix} = \{a,ck\} \boxtimes \begin{bmatrix} \{1\} \\ \{1\} \end{bmatrix}$

4. $\begin{bmatrix} \{a\} & \{c\} \\ \{b\} & \{a\} \end{bmatrix} \boxtimes \begin{bmatrix} \{1\} \\ \{ \frac{\sqrt{bc}}{d} \} \end{bmatrix} = \{a, \sqrt{bc}\} \boxtimes \begin{bmatrix} \{1\} \\ \{ \frac{\sqrt{bc}}{d} \} \end{bmatrix}$

For the necessity part in (4), consider the matrix $A=\begin{bmatrix} \{a\} & \{c\} \\ \{b\} & \{d\} \end{bmatrix}$. Assume that $a \geq d$, and $a^2 > bc$. Then $\nu(A) = a$, and $\rho(A) = \frac{(a+d) + \sqrt{(a-d)^2 + 4bc}}{2}$.

So we require $\begin{bmatrix} \{a\} & \{c\} \\ \{b\} & \{d\} \end{bmatrix} \boxtimes \begin{bmatrix} x \\ y \end{bmatrix} = \{a, \mu\} \boxtimes \begin{bmatrix} x \\ y \end{bmatrix}$ (320)

So we have

$$ax \boxplus cy = ax \boxplus \mu x \implies cy = \mu x$$ (321)

$$bx \boxplus dy = ay \boxplus \mu y$$ (322)

If $c=\emptyset$, then the matrix is reducible, otherwise we have $y = \frac{\mu}{c} x$. 

126
Therefore Equation (322) becomes
\[
x \left\{ b, \frac{d\mu}{c} \right\} = x \left\{ \frac{a\mu}{c}, \frac{\mu^2}{c} \right\}
\]  
(323)

If \( x=\emptyset \), then from Equation (321) \( y=\emptyset \), which can not occur. Therefore Equation (323) implies that
\[
\left\{ b, \frac{d\mu}{c} \right\} = \left\{ \frac{a\mu}{c}, \frac{\mu^2}{c} \right\}
\]  
(324)

So there are two cases to consider:

(I) \[
\begin{aligned}
bc &= a\mu \\
\frac{d\mu}{c} &= \mu^2
\end{aligned}
\]

Therefore, \( \mu=d \) or \( \mu=\emptyset \).

\( d=\mu \implies ad=bc \). In this case the matrix \( A \) is singular. If \( \mu=\emptyset \) then \( d=\emptyset \) and \( bc=\emptyset \).

So either \( b=\emptyset \) or \( c=\emptyset \), and the matrix \( A \) is reducible.

(II) \[
\begin{aligned}
bc &= \mu^2 \\
\frac{d\mu}{c} &= a\mu
\end{aligned}
\]

Either \( a=d \) or \( \mu=\emptyset \). If \( \mu=\emptyset \) then \( bc=\emptyset \) and the matrix \( A \) is is reducible. Suppose \( a=d \).

So \( \mu = \sqrt{bc} \) and \( y=\frac{\sqrt{bc}}{c} x \). The eigenvalue equation of part (4) follows.

One last form to consider is \[
\begin{bmatrix}
a & c \\
b & \emptyset
\end{bmatrix}
\]. It can be shown that, in this case, the matrix must either be reducible or it must be of the form \[
\begin{bmatrix}
\emptyset & c \\
b & \emptyset
\end{bmatrix}
\].

\( \square \)

For matrices with more than one element in each mset or larger than \( 2\times2 \), the theory becomes more difficult.

8.16 End Notes

The study of msets is a method to incorporate the theory of convex cones into linear algebra. The mset algebra can be used in much the same way that the ordinary algebra is used. The mset algebra is an attempt to keep as much information as possible about a particular problem available throughout the analysis. This certainly makes the investigation into these topics more complicated than the usual (conventional) algebra system. As may have been noticed in some of the examples earlier in this section, and particularly in Section 8.3, one may wish to discuss a homomorphism from \( 3^5 \) to \( S \). This is the same definition given in Definition 8.10.
Definition 8.116. Define the function $\psi : 3^S \rightarrow S$

$$\psi(\alpha) = \bigoplus_k \alpha_k$$  (325)

Proposition 8.117. $\psi$ is a homomorphism from $3^S$ to $S$.

1. $\psi(\alpha \uplus \beta) = \psi(\alpha) \oplus \psi(\beta)$
2. $\psi(\alpha \boxtimes \beta) = \psi(\alpha) \otimes \psi(\beta)$
3. $\psi(\emptyset) = 0$

Proof.

(8.117.1)

$$\psi(\alpha \uplus \beta) = \bigoplus_k (\alpha \uplus \beta)$$  (326)

$$= \left( \bigoplus_i \alpha_i \right) \oplus \left( \bigoplus_j \beta_j \right)$$  (327)

$$= \psi(\alpha) \oplus \psi(\beta)$$  (328)

(8.117.2)

$$\psi(\alpha \boxtimes \beta) = \bigoplus_k (\alpha \boxtimes \beta)$$  (329)

$$= \bigoplus_k (\uplus_i \uplus_j \alpha_i \beta_j)$$  (330)

$$= \left( \bigoplus_k (\uplus_i \alpha_i) \right) \otimes \left( \bigoplus_k (\uplus_j \beta_j) \right)$$  (331)

$$= \left( \bigoplus_i \alpha_i \right) \otimes \left( \bigoplus_j \beta_j \right)$$  (332)

$$= \psi(\alpha) \otimes \psi(\beta)$$  (333)

(8.117.3) is follows from the definition.

By using the homomorphism, some information is lost in going from $3^S$ to $S$, but the algebra may become much easier. As an example we consider the set $S = \mathbb{R}$ with the usual operations.
Example 8.118. Consider the equation: $\alpha x = \beta$.

$$ax = \beta \quad (334)$$
$$\psi(\alpha x) = \psi(\beta) \quad (335)$$
$$\left( \sum_i \alpha_i \right) \cdot \left( \sum_j x_j \right) = \left( \sum_k \beta_k \right) \quad (336)$$
$$\left( \sum_j x_j \right) = \frac{\left( \sum_k \beta_k \right)}{\left( \sum_i \alpha_i \right)} \quad (337)$$

In the conventional algebra this would be written as $x = \frac{\beta}{\alpha}$.

Note 8.119. We cannot take a matrix equation in $\mathbb{R}$, translate it to the Mset algebra, and get a true mset equation.

Example 8.120. Consider the matrix equation:

$$\begin{bmatrix} 2 & 3 \\ 5 & 4 \end{bmatrix} \begin{bmatrix} 2 \\ 4 \end{bmatrix} = \begin{bmatrix} 16 \\ 26 \end{bmatrix}$$

This equation is true in $\mathbb{R}$, but the corresponding equation is not true in the Mset algebra.

$$\begin{bmatrix} \{2\} & \{3\} \\ \{5\} & \{4\} \end{bmatrix} \neq \begin{bmatrix} \{16\} \\ \{26\} \end{bmatrix} \quad \text{since} \quad \begin{bmatrix} \{4,12\} \\ \{10,16\} \end{bmatrix} \neq \begin{bmatrix} \{16\} \\ \{26\} \end{bmatrix}$$

It should be pointed out though that, if we apply the map $\psi$ to the last equation above, we get a true statement.
9 Characteristic Polynomial in Max-Times Algebra

9.1 Algorithm

In the past sections, we have developed an equation which is satisfied by the given equation. Although this equation can be applied to many different algebra systems, we concentrate on the Max-Times Algebra system in this section.

We would like to find an algorithm which can be used to find the characteristic equation of a matrix in the Max-Times Algebra system without using all of the knowledge of the mset theory.

We begin with the algorithm to find the Characteristic Equation for a Matrix in $\mathfrak{M}^*$. The proof of the algorithm comes later in the section.

**Algorithm 9.1.** Given matrix $A_{n \times n} \in \mathfrak{M}^*_{n \times n}$.

1. For $k = 1$ to $n$

2. Let $\gamma^e_k$ = set of all terms in $|A^e_{\phi}|$ which are obtained from even permutations, where $\phi \in C^e_k$.

3. Let $\gamma^o_k$ = set of all terms in $|A^o_{\phi}|$ which are obtained from odd permutations, where $\phi \in C^o_k$.

4. If $\gamma^e_k = \gamma^o_k = \{\}$ then $c_k = 0$, and goto Step (13).

5. Let $\Gamma^e_k = \max \{\gamma^e_k\}$. If $\gamma^e_k = \emptyset$ then $\Gamma^e_k = 0$.

6. Let $\Gamma^o_k = \max \{\gamma^o_k\}$. If $\gamma^o_k = \emptyset$ then $\Gamma^o_k = 0$.

7. If $\Gamma^e_k \neq \Gamma^o_k$ then goto Step (9)

8. If $\Gamma^e_k = \Gamma^o_k$ then $\gamma^o_k := \gamma^e_k \setminus \Gamma^e_k$ and $\gamma^o_k := \gamma^o_k \setminus \Gamma^o_k$. Goto (4).

9. Let $\Gamma^e_k = \max \{\zeta \mid \zeta \in \Gamma^e_k \cup \Gamma^o_k \}$.

10. Let $\zeta_k$ = the permutation in $\Gamma^e_k \cup \Gamma^o_k$ which yields the maximum.

11. Let $\text{sgn}(\zeta) = \begin{cases} 1 & \text{if } \zeta \text{ is an even permutation} \\ -1 & \text{if } \zeta \text{ is an odd permutation} \end{cases}$

12. Let $c_k = (-1)^k \cdot \text{sgn}(\zeta_k) \cdot \Gamma^e_k$.

13. Next $k$

14. The terms with $c_k > 0$ are on the LHS of the equation, and terms with $c_k < 0$ are on the RHS of the equation. This yields an equation of the form:

$$\lambda^k \bigoplus \left( \bigoplus_{c_k > 0} c_k \lambda^{n-k} \right) = \bigoplus_{c_k < 0} (-1 \cdot c_k) \lambda^{n-k}$$

(338)
Justification. The justification for the above algorithm will be developed shortly, in particular, see Theorem 9.11.

First, let us look at a few examples.

9.2 Examples

A few examples will be quite illustrative.

**Example 9.2.** Find the characteristic equation for: $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 7 & 9 \\ 5 & 1 & 3 \end{bmatrix} \in \mathbb{M}_{3 \times 3}$.  

$\Gamma_1 = \{1,7,3\}, \quad \Gamma_2 = \{3,7,21\}, \quad \Gamma_2^* = \{8,9,15\}$  
$\Gamma_3 = \{12,21,90\}, \quad \Gamma_3^* = \{9,24,105\}$  
$\Gamma_1^* = 7, \quad \Gamma_2^* = 21, \quad \Gamma_3^* = 105$  
$c_1 = (-1)^1 \ast (1) \ast 7 = -7$ \hspace{1em} Note: $\zeta_7 \in \Gamma_1^*$  
$c_2 = (-1)^2 \ast (1) \ast 21 = 21$ \hspace{1em} Note: $\zeta_{21} \in \Gamma_2^*$  
$c_3 = (-1)^3 \ast (-1) \ast 105 = -105$ \hspace{1em} Note: $\zeta_{105} \in \Gamma_3^*$

Therefore we have $P(\lambda) = \lambda^3 \boxplus 21 \boxplus \lambda \boxplus 105$, and  
$Q(\lambda) = 7 \boxdot \lambda^2$.  

And the characteristic equation is:  
$\lambda^3 \boxplus 21 \boxplus \lambda \boxplus 105 = 7 \boxdot \lambda^2$.

We can see that the matrix $A$ satisfies:  
$A^2 \boxplus 21 \boxplus A \boxplus 105 \boxplus I = 7 \boxdot A^2$, as each side of the equation is:  
$\begin{bmatrix} 105 & 98 & 126 \\ 315 & 343 & 441 \\ 105 & 70 & 105 \end{bmatrix}$

**Example 9.3.** Consider the matrix: $A = \begin{bmatrix} 1 & 5 & 2 \\ 2 & 3 & 2 \\ 3 & 0 & 3 \end{bmatrix} \in \mathbb{M}_{3 \times 3}$.  

$\Gamma_1 = \{1,3,3\}, \quad \Gamma_2 = \{3,3,9\}, \quad \Gamma_2^* = \{0,6,10\}$  
$\Gamma_3 = \{0,9,30\}, \quad \Gamma_3^* = \{0,18,30\}$  
$\Gamma_1^* = 3, \quad \Gamma_2^* = 10, \quad \Gamma_3^* = 18$  
$c_1 = (-1)^1 \ast (1) \ast 3 = -3$ \hspace{1em} Note: $\zeta_3 \in \Gamma_1^*$  
$c_2 = (-1)^2 \ast (-1) \ast 10 = -10$ \hspace{1em} Note: $\zeta_{10} \in \Gamma_2^*$  
$c_3 = (-1)^3 \ast (-1) \ast 18 = 18$ \hspace{1em} Note: $\zeta_{18} \in \Gamma_3^*$

There we see that the characteristic equation is:  
$\lambda^3 \boxplus 18 = 3 \boxdot \lambda^2 \boxplus 10 \boxdot \lambda$,  

131
and we note that the matrix $A$ satisfies: $A^3 \equiv 18I = 3A^2 \equiv 10A$. In this case we have 30 as the maximum from both an even permutation and an odd permutation of length 3, so we use 18 which is the next largest permutation product.

Define the degree of an equation in the most natural way: the degree of an equation is the largest degree of the polynomial on either side of the equal sign.

As it is with the conventional linear algebra, we ask the natural question of whether we can find a polynomial equation of smaller degree which is satisfied by the matrix.

**Example 9.4.** For the matrix $A=J_{3\times 3}$, the characteristic equation using the above algorithm is $x^3 = x^2$, but it can be checked that $x^2 = x$ is also an equation of smaller degree.

**Example 9.5.** For the matrix $A=J_{n\times n}$, the characteristic equation using the above algorithm is $x^n = x^{n-1}$, but it can be checked that $x^2 = x$ is also an equation of smaller degree.

**Example 9.6.** For the matrix $A=J_{3\times 3}-I_{3\times 3}$, the characteristic equation using the above algorithm is $x^3 = x \equiv 1$, but it can be checked that $x^2 = x \equiv 1$ is also an equation of smaller degree.

**Example 9.7.** For the matrix $A=J_{n\times n}-I_{n\times n}$, the characteristic equation using the above algorithm is $x^n = \prod_{k=2}^{n} x^{n-k}$, but it can be checked that $x^2 = x \equiv 1$ is also an equation of smaller degree.

The above four examples show that there may very well exist a polynomial equation of smaller degree which is satisfied by the given matrix. This, of course, leads to the questions:

1. How can we determine whether an equation of lower degree exists?

2. If another equation exists, how can we find it?

The following will help clarify some of the information about $\sigma$.

**Proposition 9.8.**

1. If $k$ is even, and $\sigma$ is an even permutation,
   then $\text{sign}(\sigma) = (-1)^k \text{sgn}(\sigma) = 1$

2. If $k$ is even, and $\sigma$ is an odd permutation,
   then $\text{sign}(\sigma) = (-1)^k \text{sgn}(\sigma) = -1$

3. If $k$ is odd, and $\sigma$ is an even permutation,
   then $\text{sign}(\sigma) = (-1)^k \text{sgn}(\sigma) = -1$

4. If $k$ is odd, and $\sigma$ is an odd permutation,
   then $\text{sign}(\sigma) = (-1)^k \text{sgn}(\sigma) = 1$
Note 9.9. If \(a, b \in \mathbb{R}^+\), and \(a \leq b\), then the expression \(ax^\ell \boxplus bx^\ell\) can be reduced to the expression \(bx^\ell\), i.e. \(ax^\ell \boxplus bx^\ell = bx^\ell\).

To see how Proposition 9.8 relates to the proof of Algorithm 9.1 it can be seen that the parity of \(k\) and the parity of \(\sigma\) determine which side of the equation the term will occur. This means that \(p_A^\sigma(x)\) has the terms of \(x^{n-\ell}\) which have a coefficient in which \(\sigma\) is an permutation of \(\text{par}(q)\), and \(p_A^\sigma(x)\) has the terms of \(x^{n-\ell}\) which have a coefficient in which \(\sigma\) is an permutation of \(\text{par}(q+1)\). This is yet another, possibly easier, way of classifying the terms of the equation. \(p_A^\sigma(x)=p_A^\sigma(x)\).

Example 9.10. Consider \(A=\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}\)

\[
\det(xI-A) = 0
\]

\[
x^3 - (a_{11} + a_{22} + a_{33})x^2 + (a_{11}a_{22} + a_{11}a_{33} + a_{22}a_{33} - a_{12}a_{21} - a_{13}a_{31} - a_{23}a_{32})x \\
+ (a_{11}a_{23}a_{31} + a_{11}a_{23}a_{32} + a_{12}a_{21}a_{33} + a_{11}a_{22}a_{33} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32}) = 0
\]

\[
x^3 + (a_{11}a_{22} + a_{11}a_{33} + a_{22}a_{33})x + (a_{13}a_{22}a_{31} + a_{11}a_{23}a_{32} + a_{12}a_{21}a_{33}) \\
= (a_{11} + a_{22} + a_{33})x^2 + (a_{12}a_{21} + a_{13}a_{31} + a_{23}a_{32})x \\
+ (a_{11}a_{23}a_{31} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32})
\]

Theorem 9.11 (Algorithm). Algorithm 9.1 is correct.

Proof. It was shown in Theorem 8.71, that a polynomial exists. We need to show that the part of the algorithm which requires dropping terms with equal coefficients from both sides, and take the largest coefficient for that term which is not shared by both sides.

Consider the set equation in Theorem 8.68.

Suppose that there exists \(\sigma_1\) as an “even” permutation, and \(\sigma_2\) as an “odd” permutation, both of length \(k\), with \(\omega(\sigma_1) = \omega(\sigma_2)\), and \(|\sigma_1| = |\sigma_2|\).

If \(|\sigma_1| = k\), then there is a permutation \(\pi_1\) associated with \(\sigma_1\) with \(|\pi_1| = n - k\). We can assume, without loss of generality, that \((\sigma, \pi) \in T_i^j\), and \((\sigma, \pi) \in T_i^j\). There exists \(i_1, j_1 \in S_n\) such that \(\eta_{i_1,j_1}(\sigma_1, \pi_1) = (\sigma'_1, \pi'_1)\), with \(\omega(\sigma_1)\omega(\pi_1) = \omega(\sigma'_1)\omega(\pi'_1)\), and there exists \(i_2, j_2 \in S_n\) such that \(\eta_{i_2,j_2}(\sigma_2, \pi_2) = (\sigma'_2, \pi'_2)\), with \(\omega(\sigma_2)\omega(\pi_2) = \omega(\sigma'_2)\omega(\pi'_2)\).

This means that the element of the set corresponding to \((\sigma_1, \pi_1)\) on one side and \((\sigma'_1, \pi'_1)\) on the other side occur is the same element.

Therefore we can delete these two elements from both sides from the equation (Equation (8.68)). Likewise, we can drop the element on each side corresponding to \((\sigma_2, \pi_2)\) on one side and \((\sigma'_2, \pi'_2)\) on the other side. After dropping the identical elements from both sides of the equation, we apply the maximum-function to both sides to get another equation which must hold.
Note 9.12. Although the equation given by Theorem 8.71 is a polynomial equation which is satisfied by the matrix \( A \), it may have terms of the same degree on each side of the equation. In this thesis we refer to the polynomial equation derived from Algorithm 9.1 as THE CHARACTERISTIC POLYNOMIAL of the matrix \( A \).

As an example we can show equality of the sets in the 2x2 case.

Example 9.13. \( A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \).

\[ A^2 = \begin{bmatrix} \{a_{11}a_{11}, a_{12}a_{21}\} & \{a_{11}a_{12}, a_{12}a_{22}\} \\ \{a_{11}a_{21}, a_{22}a_{21}\} & \{a_{21}a_{12}, a_{22}a_{22}\} \end{bmatrix} . \]

We show equality of the sets in the identity (equation):

\[
\begin{array}{c|c|c|c|c}
\langle \omega(\sigma) \rangle \circ A^2 & \langle \omega(\sigma) \rangle \circ I & \langle \omega(\sigma) \rangle \circ A & \langle \omega(\sigma) \rangle \circ I \\
|\sigma| = 0 & |\sigma| = 2 & |\sigma| = 1 & |\sigma| = 2 \\
|\pi| = 2 & |\pi| = 0 & |\pi| = 1 & |\pi| = 0 \\
sig(\sigma) = 1 & sig(\sigma) = 1 & sig(\sigma) = -1 & sig(\sigma) = -1
\end{array}
\]

where

\[
\begin{array}{c|c|c|c|c}
\langle \omega(\sigma) \rangle \circ A^2 = \langle 1 \rangle \circ A^2 & \langle \omega(\sigma) \rangle \circ I = \langle a_{11}a_{22} \rangle \circ I \\
|\sigma| = 0 & |\sigma| = 2 \\
|\pi| = 2 & |\pi| = 0 \\
sig(\sigma) = 1 & sig(\sigma) = 1
\end{array}
\]

\[
\begin{array}{c|c|c|c|c}
\langle \omega(\sigma) \rangle \circ A = \langle a_{11}, a_{22} \rangle \circ A & \langle \omega(\sigma) \rangle \circ I = \langle a_{12}a_{21} \rangle \circ I \\
|\sigma| = 1 & |\sigma| = 2 \\
|\pi| = 1 & |\pi| = 0 \\
sig(\sigma) = -1 & sig(\sigma) = -1
\end{array}
\]

So,
\[
\bigcup \omega(\sigma) \circ A^2 \bigcup \omega(\sigma) \circ I
\]

\[
|\sigma| = 0 \quad |\sigma| = 2
\]

\[
|\pi| = 2 \quad |\pi| = 0
\]

\[
sig(\sigma) = 1 \quad sig(\sigma) = 1
\]

\[
\begin{aligned}
\{1\} \cup
\begin{bmatrix}
\{a_{11}a_{11},a_{12}a_{21}\} & \{a_{11}a_{12},a_{12}a_{22}\} \\
\{a_{11}a_{21},a_{22}a_{21}\} & \{a_{21}a_{12},a_{22}a_{22}\}
\end{bmatrix}
\cup
\begin{bmatrix}
\{1\} & \{0\} \\
\{0\} & \{1\}
\end{bmatrix}
\end{aligned}
\]

\[
\begin{aligned}
\{a_{11}a_{11},a_{12}a_{21}\} & \{a_{11}a_{12},a_{12}a_{22}\} \\
\{a_{11}a_{21},a_{22}a_{21}\} & \{a_{21}a_{12},a_{22}a_{22},a_{11}a_{22}\}
\end{aligned}
\]

\[
\begin{aligned}
\{a_{11},a_{22}\} \circ \{a_{11}\} \cup \{a_{12}a_{21}\} & \{a_{11},a_{22}\} \cup \{a_{12}\} \\
\{a_{11},a_{22}\} \cup \{a_{21}\} & \{a_{22},a_{11}\} \cup \{a_{21}a_{12}\}
\end{aligned}
\]

\[
\begin{aligned}
\{a_{11},a_{22}\} & \circ A \cup \{a_{12}a_{21}\} \circ I
\end{aligned}
\]

\[
\begin{aligned}
\bigcup \omega(\sigma) \circ A & \bigcup \omega(\sigma) \circ I
\end{aligned}
\]

\[
|\sigma| = 1 \quad |\sigma| = 2
\]

\[
|\pi| = 1 \quad |\pi| = 0
\]

\[
sig(\sigma) = -1 \quad sig(\sigma) = -1
\]

Using the notation of \(\sigma^k\), and \(\sigma^k\), the above equation can be written briefly as:

\[
\sigma^0_0 \circ A^2 \cup \sigma^k_0 \circ A \cup \sigma^k_0 \circ I = \sigma^0_0 \circ A^2 \cup h \circ A \cup \sigma^k_0 \circ I
\]

where

\[
\begin{aligned}
\sigma^0_0 & = \{1\} & \sigma^0_1 & = \{0\}
\end{aligned}
\]

\[
\begin{aligned}
\sigma^k_0 & = \{a_{11},a_{22}\} & \sigma^k_0 & = \{0,0\}
\end{aligned}
\]

\[
\begin{aligned}
\sigma^k_2 & = \{a_{11}a_{22}\} & \sigma^k_5 & = \{a_{12}a_{21}\}
\end{aligned}
\]

**Example 9.14.** For the 3×3 matrix \(A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \).
The characteristic equation can be written as:

\[
\bigoplus \omega(\sigma) \odot A^{3} \bigoplus \omega(\sigma) \odot A \bigoplus \omega(\sigma) \odot I
\]

\[
|\sigma| = 0 \quad |\sigma| = 2 \quad |\sigma| = 3
\]

\[
|\pi| = 3 \quad |\pi| = 1 \quad |\pi| = 0
\]

\[
sig(\sigma) = 1 \quad sig(\sigma) = 1 \quad sig(\sigma) = 1
\]

\[
= \bigoplus \omega(\sigma) \odot A^{2} \bigoplus \omega(\sigma) \odot A \bigoplus \omega(\sigma) \odot I
\]

\[
|\sigma| = 1 \quad |\sigma| = 2 \quad |\sigma| = 3
\]

\[
|\pi| = 2 \quad |\pi| = 1 \quad |\pi| = 0
\]

\[
sig(\sigma) = -1 \quad sig(\sigma) = -1 \quad sig(\sigma) = -1
\]

which simplifies to:

\[
\{1\} \odot A^{3} \uplus \{a_{11}, a_{22}, a_{33}, a_{22} a_{33}\} \odot A \uplus \{a_{13} a_{22} a_{31}, a_{11} a_{23} a_{32}, a_{12} a_{21} a_{33} \odot I
\]

\[
= \{a_{11}, a_{22}, a_{33}\} \odot A^{2} \uplus \{a_{12} a_{21}, a_{13} a_{31}, a_{23} a_{32}\} \odot A \uplus \{a_{11} a_{22} a_{33}, a_{12} a_{23} a_{31}, a_{13} a_{21} a_{32} \odot I
\]

This can be written more compact using the previous definitions as:

\[
\sigma^{3} \odot A \uplus \sigma^{2} \odot A \uplus \sigma \odot I = \sigma^{3} \odot A^{2} \uplus \sigma^{2} \odot A \uplus \sigma \odot I
\]

With the theorems above we can add the following theorem.

**Theorem 9.15.** Given a matrix \( A \), and a permutation matrix \( P \), the characteristic polynomials of \( A \) and \( M=P^{-1}A \) are the same.

**Proof.** The matrix \( M \) has the same graph as \( A \), except that the nodes have been relabeled. The set of “partial determinants” of the principal minors of \( M \) and the set of “partial determinants” of the principal minors of \( A \) are the same set. \( \square \)

### 9.3 Eigenvalues and Roots of the Characteristic Equation

**Example 9.16.** Consider the matrix: \( A = \begin{bmatrix} 1 & 4 & 9 \\ 0 & 2 & 6 \\ 0 & 0 & 3 \end{bmatrix} \).

Matrix \( A \) has the characteristic equation: \( \lambda^{3} \uplus 6\lambda = 3\lambda^{2} \uplus 6 \). This equation has \( \lambda = 1, \lambda = 2, \) and \( \lambda = 3 \) as roots. We see that for this matrix 1, 2, and 3 are all eigenvalues for the matrix.
\[
\begin{bmatrix}
1 & 4 & 9 \\
0 & 2 & 6 \\
0 & 0 & 3 \\
\end{bmatrix}
= 2 \cdot \begin{bmatrix}
1 \\
0 \\
1 \\
\end{bmatrix}
= 2 \cdot \begin{bmatrix}
4 \\
2 \\
2 \\
\end{bmatrix}
= 2 \cdot \begin{bmatrix}
3 \\
6 \\
3 \\
\end{bmatrix}
= 3 \cdot \begin{bmatrix}
1 \\
0 \\
0 \\
\end{bmatrix}.
\]

**Example 9.17.** Consider the matrix: 
\[
B = \begin{bmatrix}
3 & 4 & 9 \\
0 & 2 & 6 \\
0 & 0 & 1 \\
\end{bmatrix}.
\]

This matrix has the same characteristic equation as the matrix in Example 9.16, namely 
\(\lambda^3 \equiv 6\lambda = 3\lambda^2 \equiv 6\). Also the equation has the same roots, namely, \(\lambda = 1, \lambda = 2, \) and \(\lambda = 3\). But this matrix has \(\lambda = 3\) as the only eigenvalue. Here it can be checked that 
\[
\begin{bmatrix}
3 & 4 & 9 \\
0 & 2 & 6 \\
0 & 0 & 1 \\
\end{bmatrix}
= 3 \cdot \begin{bmatrix}
1 \\
0 \\
0 \\
\end{bmatrix},
\]
and \(\lambda = 3\) is the only eigenvalue.

Notice that both matrices above, Examples 9.16 and 9.17, have \(\lambda = 3\) as an eigenvalue, and \(\lambda = 3\) is a root of the characteristic equation of both matrices. Is it true that the maximum eigenvalue of a matrix, \(\nu(A)\), is always a solution to the characteristic equation? The answer is certainly yes, just as it is in the conventional algebra. The proof is given in Theorem 9.27.

### 9.4 Algorithm for \(\nu(A)\)

In this section, we propose an algorithm which can be used to calculate the maximum eigenvalue of a matrix, denoted as \(\nu(A)\), from the characteristic equation in the Max-Times Algebra.

**Algorithm 9.18.**

Suppose that \(p_A^+(x) = p_A^-(x)\) is the characteristic equation of \(A\).

(a) \(p_A^+(x) = x^n + a_1 x^{n_1} + a_2 x^{n_2} + \cdots + a_{n_k} x^{n_{k}}\)

(b) \(p_A^-(x) = a_{m_1} x^{m_1} + a_{m_2} x^{m_2} + \cdots + a_{m_{m}} x^{m_{m}}\)

(c) \(n_i\)'s and \(m_i\)'s are all distinct, and \(m_1 = n - 1\)

(2) For \(i = 1, \ldots, \ell\) 

set \(x^n = a_{m_i} x^{m_i}\) 

divide both sides by \(x^{m_i}\), yielding \(x^{n - m_i} = a_{m_i}\) 

set \(b_i = (x^{n - m_i}) = (a_{m_i})^{\frac{1}{x^{m_i}}}\) 

end

(3) \(\nu(A) = \max_{i=1}^{\ell} b_i = b_1 \oplus b_2 \oplus \cdots \oplus b_\ell\).
(4) End.

Theorem 9.26 provides the proof of the above algorithm. Included here is the proof of the $2 \times 2$, and $3 \times 3$ cases. Also included is the $4 \times 4$ case to show more detail of the cycle structure of the coefficients of the terms of polynomial equation. This will help lead to the proof of the general case.

**Example 9.19.** $A = \begin{bmatrix} a & c \\ b & d \end{bmatrix}$

The characteristic equation for the matrix is:

$x^2 \equiv ad = (a \equiv d)x \equiv bc$

This leads to the two equations:

1. $x^2 = (a \equiv d)x \quad \implies \quad b_1 = (a \equiv d)$
2. $x^2 = bc \quad \implies \quad b_2 = \sqrt{bc}$.

Therefore, $\nu(A) = b_1 \equiv b_2 = a \equiv d \equiv \sqrt{bc}$.

Before showing the $3 \times 3$ case, we need a lemma, whose proof is quite simple.

**Lemma 9.20.** If $a, b, c \geq 0$, and $\max(a, b, c) = a$, then $a^3 \geq abc$.

**Proof.** The proof follows from the fact that $a^3 \geq abc$. □

**Example 9.21.** $A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$

The characteristic equation for the matrix is:

\[
x^3 \equiv (a_{11}a_{22} \equiv a_{11}a_{33} \equiv a_{22}a_{33})x^2 \equiv (a_{13}a_{22}a_{31} \equiv a_{11}a_{23}a_{32} \equiv a_{12}a_{21}a_{33})x \\
= (a_{11} \equiv a_{22} \equiv a_{33})x^2 \equiv (a_{12}a_{21} \equiv a_{13}a_{31} \equiv a_{23}a_{32})x \\
\equiv (a_{11}a_{22}a_{33} \equiv a_{12}a_{23}a_{31} \equiv a_{13}a_{21}a_{32})
\]

This leads to the three equations:

1. $x^3 = (a_{11} \equiv a_{22} \equiv a_{33})x^2$, so $b_1 = (a_{11} \equiv a_{22} \equiv a_{33})$
2. $x^3 = (a_{12}a_{21} \equiv a_{13}a_{31} \equiv a_{23}a_{32})x$, so $b_2 = \sqrt{(a_{12}a_{21} \equiv a_{13}a_{31} \equiv a_{23}a_{32})} = \sqrt{a_{12}a_{21}} \equiv \sqrt{a_{13}a_{31}} \equiv \sqrt{a_{23}a_{32}}$

138
(3) \[ x^3 = (a_{11}a_{22}a_{33} \oplus a_{12}a_{23}a_{31} \oplus a_{13}a_{21}a_{32}), \]
so
\[ b_3 = \sqrt[3]{(a_{11}a_{22}a_{33} \oplus a_{12}a_{23}a_{31} \oplus a_{13}a_{21}a_{32})} \]
\[ = (\sqrt[3]{a_{11}a_{22}a_{33}} \oplus \sqrt[3]{a_{12}a_{23}a_{31}} \oplus \sqrt[3]{a_{13}a_{21}a_{32}}) \]

Therefore,
\[ \nu(A) = b_1 \oplus b_2 \oplus b_3 \]
\[ = a_{11} \oplus a_{22} \oplus a_{33} \oplus \sqrt[3]{a_{12}a_{21}a_{31}} \oplus \sqrt[3]{a_{13}a_{31}a_{32}} \]
\[ \oplus \sqrt[3]{a_{12}a_{23}a_{31}} \oplus \sqrt[3]{a_{13}a_{21}a_{32}} \]
\[ a_{11} \oplus a_{22} \oplus a_{33} \oplus \sqrt[3]{a_{12}a_{21}a_{31}} \oplus \sqrt[3]{a_{13}a_{31}a_{32}} \]
\[ \oplus \sqrt[3]{a_{12}a_{23}a_{31}} \oplus \sqrt[3]{a_{13}a_{21}a_{32}} \]

The last step in the above equation results from removing \( \sqrt[3]{a_{11}a_{22}a_{33}} \) by use of Lemma 9.20, where \( a=a_{11}, b=a_{22}, \) and \( c=a_{33}. \)

The partial permutations can be split into even or odd permutations by looking at the number of transpositions needed to achieve the permutation. Here we are looking for permutations on 3 elements, \( S_3. \) Table 4 on page 139 shows the “cycles” for the \( 3 \times 3 \) matrix.

Table 4: Partial Permutations in \( 3 \times 3 \) characteristic polynomial

To gain more insight into the problem the \( 4 \times 4 \) case in included. It is quite illustrative.
The following is the (long) characteristic equation for the $4 \times 4$ matrix.

$$x^4 + (a_{11}a_{22} + a_{11}a_{33} + a_{11}a_{44} + a_{22}a_{33} + a_{22}a_{44} + a_{33}a_{44})x^2$$
$$+ (a_{11}a_{23}a_{32} + a_{11}a_{24}a_{42} + a_{11}a_{34}a_{43} + a_{13}a_{22}a_{31} + a_{14}a_{22}a_{41})$$
$$+ a_{22}a_{34}a_{43} + a_{12}a_{21}a_{33} + a_{14}a_{33}a_{41} + a_{24}a_{33}a_{42} + a_{12}a_{21}a_{44}$$
$$+ a_{13}a_{31}a_{44} + a_{23}a_{32}a_{44} + (a_{11}a_{22}a_{33}a_{44} + a_{11}a_{23}a_{34}a_{42})$$
$$+ a_{11}a_{24}a_{32}a_{43} + a_{12}a_{21}a_{34}a_{43} + a_{12}a_{24}a_{33}a_{41} + a_{12}a_{23}a_{31}a_{44}$$
$$+ a_{13}a_{24}a_{31}a_{42} + a_{13}a_{21}a_{32}a_{44} + a_{13}a_{22}a_{34}a_{41}$$
$$+ a_{14}a_{21}a_{33}a_{42} + a_{14}a_{22}a_{31}a_{43} + a_{14}a_{23}a_{32}a_{41})$$

$$= (a_{11} + a_{22} + a_{33} + a_{44})x^3 + (a_{12}a_{21} + a_{13}a_{31} + a_{14}a_{41} + a_{23}a_{32} + a_{24}a_{42} + a_{34}a_{43})x^2$$
$$+ (a_{11}a_{23}a_{32} + a_{11}a_{24}a_{42} + a_{11}a_{33}a_{44} + a_{12}a_{23}a_{31} + a_{12}a_{24}a_{41} + a_{13}a_{21}a_{32}$$
$$+ a_{13}a_{34}a_{41} + a_{14}a_{21}a_{42} + a_{14}a_{31}a_{43} + a_{22}a_{34}a_{44} + a_{23}a_{31}a_{42} + a_{24}a_{32}a_{43})x$$
$$+ (a_{11}a_{22}a_{34}a_{43} + a_{11}a_{23}a_{32}a_{44} + a_{11}a_{24}a_{33}a_{42} + a_{12}a_{21}a_{33}a_{44} + a_{12}a_{23}a_{34}a_{41}$$
$$+ a_{12}a_{24}a_{31}a_{43} + a_{13}a_{21}a_{34}a_{42} + a_{13}a_{22}a_{31}a_{44} + a_{13}a_{24}a_{32}a_{41} + a_{14}a_{21}a_{32}a_{43}$$
$$+ a_{14}a_{22}a_{33}a_{41} + a_{14}a_{23}a_{31}a_{42})$$

The partial permutations can be split up into even or odd permutations by looking at the number of transpositions needed to achieve the permutation. Table 5 on page 141 summarizes the results.

</tbody>
</table>

Table 5: Partial Permutations in 4×4 characteristic polynomial
We need the following lemmas to prove the general case. Lemma 9.22 is a general lemma which covers the case for all diagonal elements.

**Lemma 9.22.** If  \( \max_{1 \leq i \leq k} (a_i) = a_* \), then  \( a_* \geq \left( \prod_{i=1}^{k} a_i \right)^{\frac{1}{k}} \)

*Proof.*

\[
(a_*)^k \geq \prod_{i=1}^{k} a_i
\]

\( \square \)

Lemma 9.23 is more general than Lemma 9.22. It states that the maximal element of a set is at least as large as the qth root of any product of q elements of the set, i.e. the largest element is larger than the geometric mean of any q elements.

**Lemma 9.23.** If  \( \max_{i \in \Omega} (a_i) = a_* \), then  \( a_* \geq \left( \prod_{j=1}^{q} a_{i_j} \right)^{\frac{1}{q}} \),  \( \forall q \leq k, \forall i_j \in \Omega \)

*Proof.*  \( a_*^q \geq \prod_{j=1}^{q} a_{i_j} \)

\( \square \)

Lemma 9.24 states that the maximum geometric mean of any cycle of  \( G(A) \) is greater than the geometric mean of two separate cycles concatenated together.

**Lemma 9.24.** If  \( \tau \) is the k-cycle of maximum geometric mean of the graph  \( G(A) \), i.e.  \( \nu(A) = (\omega(\tau))^{\frac{1}{k}} \), where  \( k = \ell(\tau) \), then for any  \( m_1 \)-cycle  \( \xi_1 \), and  \( m_2 \)-cycle  \( \xi_2 \), with  \( k = m_1 + m_2 \),

\[
(\omega(\tau))^{\frac{1}{k}} \geq (\omega(\xi_1)\omega(\xi_2))^{\frac{1}{m_1+m_2}}
\]

*Proof.* We assume that  \( \omega(\tau) \geq 0, \omega(\xi_1) \geq 0, \omega(\xi_2) \geq 0. \)

\[
(\omega(\tau))^{\frac{1}{k}} \geq (\omega(\xi_1))^{\frac{1}{m_1}} \quad \text{and} \quad (\omega(\tau))^{\frac{1}{k}} \geq (\omega(\xi_2))^{\frac{1}{m_2}}
\]

\[
(\omega(\tau))^{m_1} \geq (\omega(\xi_1))^k \quad \text{and} \quad (\omega(\tau))^{m_2} \geq (\omega(\xi_2))^k
\]

\[
(\omega(\tau))^{m_1+m_2} \geq (\omega(\xi_1)\omega(\xi_2))^k
\]

\[
(\omega(\tau))^{\frac{1}{k}} \geq (\omega(\xi_1)\omega(\xi_2))^{\frac{1}{m_1+m_2}}
\]

\( \square \)

**Note 9.25.** The above lemma, Lemma 9.24, can be extended at once to more than just the concatenation of two cycles.

142
We are now ready to prove that the algorithm given in Section 9.4 is correct as a method to calculate \( \nu(A) \).

**Theorem 9.26.** Algorithm 9.18 is correct.

**Proof.**

(1) First we must show that the coefficient of \( x^{n-q} \) on the RHS of the equation is the sum of all real “q-cycles” plus possibly some other dominated terms, and therefore all coefficients on the LHS are “pseudo q-cycles” which are “products” of cycles of length less than q whose sum is equal to q. Fix q, and suppose that \( \sigma \) is a cycle of length q, then \( \text{sgn}(\sigma) = (-1)^q \text{sgn}(\sigma) = (-1)^q(-1)^{q-1} = -1 \). Therefore \( \omega(\sigma) \) appears on the RHS of the characteristic polynomial — i.e., \( \omega(\sigma)x^{n-q} \) is a term of \( p_A(x) \).

(2) Next, we must show that \( \nu(A) \) is at least as large as any other of the \( b_{18} \). Fix q. Consider the coefficient, \( \alpha_q \), of the term \( \alpha_q x^{n-q} \) of \( p_A(x) \). We know from part (1) that all q-cycles are elements (summands) of \( \alpha_q \). What are the other elements of the \( \alpha_q \)? Since all elements of \( \alpha_q \) are q-permutations of \( S_n \), then the elements are either q-cycles or they are products of cycles of lengths less than q, but whose length sum q. For example, see Table 4, or Table 5. By Lemma 9.24, we know that \( \nu(A) \) is greater than or equal to any other element of \( \alpha_q \).

**Theorem 9.27.** \( \nu(A) \) is a root of the characteristic equation.

**Proof.** Using the same reasoning of part (2) of the proof of Theorem 9.26, and using Lemma 9.24, \( \nu(A) \) is also greater than any element of the coefficient of \( \alpha_q x^k \) on the LHS of the characteristic equation. Therefore, we see, by Lemma 9.24, that \( p_A^*(\nu(A)) = (\nu(A))^n \) because all other terms of the polynomial are dominated by \( \nu(A) \).

Therefore \( p_A^*(\nu(A)) = p_A^*(\nu(A)) \)

**9.5 Companion Matrix**

In the previous sections we have discussed the characteristic equation for matrices in the Max-Times Algebra system.

An obvious question to consider is whether for any given equation in the Max-Times Algebra system, does a matrix exist which has this given equation as its characteristic equation?

We answer this question in this section. As we see some equations do have an associated matrix, and some equations do not. We begin with the simple case of a class of equations for which an associated matrix exists.
If we are given an equation of the form
\[ \lambda^n = \prod_{i=1}^{n} a_i \lambda^{n-i} \] (339)
then the companion matrix for this equation is
\[
L = \begin{bmatrix}
0 & 1 & 0 & 0 & \cdots & 0 & 0 \\
0 & 0 & 1 & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \cdots & 0 & 1 \\
a_n & a_{n-1} & a_{n-2} & \cdots & a_2 & a_1 \\
\end{bmatrix}
\] (340)

**Example 9.28.**

For the equation \( \lambda^3 = 5\lambda^2 + 4\lambda + 3 \), the companion matrix is \( A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 3 & 4 & 5 \end{bmatrix} \).

**Theorem 9.29.** For the Companion matrix of a polynomial equation, there is no polynomial equation of smaller degree which is satisfied by the matrix.

**Proof.**

Consider the matrix \( L_{n\times n} = \begin{bmatrix} 0 & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 0 & 1 \\ a_n & a_{n-1} & a_{n-2} & \cdots & a_2 & a_1 \end{bmatrix} \)

Then we have the following:
\[
\begin{align*}
e^T_1 \otimes L &= e^T_2 \\
e^T_1 \otimes L^2 &= e^T_3 \\
&\vdots \\
e^T_1 \otimes L^{n-1} &= e^T_n
\end{align*}
\] (341) (342) (343)

Suppose that there exists a polynomial equation \( p_L^k(x) = p_L^r(x) \) of smaller degree which is satisfied by the matrix. Therefore there exists a \( k \in \mathbb{N} \) and \( r \in \mathbb{N} \) such that degree\((p^k_L(x))=k\), and degree\((p^r_L(x))=r\), with \( r<k<n \). Then from the Equations (341) above, \( L_{1,k+1}^k = 1 \), while \( L_{1,k+1}^j = 0 \), for all \( j<k \), in particular, for all \( j\leq r \). Therefore \( [p_L^k(L)]_{1,k+1} = 1 \), while \( [p_L^r(L)]_{1,k+1} = 0 \). So, no such equation can exist.

The theory becomes more difficult for polynomial equations with more than one term on the LHS. The following examples illustrate some of the difficulty.
Example 9.30. Are there polynomial equations which are not the characteristic equation for any matrix?
This can certainly be answered in the affirmative, as the polynomial equation $x^2 + 4 = x$ does not have any solutions. Therefore it is not the characteristic equation for any matrix. Since $\nu(A)$ must be a root of the characteristic polynomial, then an equation with no solutions can not be the characteristic equation for a matrix.

Example 9.31. If a polynomial equation has a solution then is it the characteristic equation for some matrix?
A polynomial equation with a solution is not sufficient to have a companion equation. The polynomial equation $x^3 + 16x = 2x^2 + 1$ has $x = \frac{1}{16}$ as a solution. It can be shown that this equation can not be the characteristic equation for any $3 \times 3$ matrix. To see this, note that $\max(a_{11}, a_{22}, a_{33})=2$, and $\max(a_{11}a_{22}, a_{11}a_{33}, a_{22}a_{33})=16$, which is impossible in the set $\mathbb{R}^+$. 
9.6 Characteristic Equation of Block Matrices in $\mathfrak{M}^r$.

As we have seen in the previous sections, given a matrix $A$ in the Max-Times Algebra, we can find an equation which is satisfied by the matrix.

Namely, for a matrix $A$, we have an equation $p^+_A(x) = p^-_A(x)$ such that $p^+_A(A) = p^-_A(A)$.

**Partitioned Matrices (Reducible Matrix)**

Let $M=\begin{bmatrix} A & 0 \\ B & D \end{bmatrix}$. In this section we develop a characteristic equation associated with the matrix $M$.

The following Theorem satisfies this problem.

**Theorem 9.32.** Let $M=\begin{bmatrix} A & 0 \\ B & D \end{bmatrix}$. Let $p^+_A(x) = p^-_A(x)$ be the characteristic equation for the submatrix $A$, and let $p^+_D(x) = p^-_D(x)$ be the characteristic equation for the submatrix $D$. Then the characteristic equation for $M$ is: $p^+_M(x) = p^-_M(x)$, where

$p^+_M(x) = p^+_A(x)p^+_D(x) \boxplus p^-_A(x)p^-_D(x)$, and

$p^-_M(x) = p^+_A(x)p^-_D(x) \boxplus p^-_A(x)p^+_D(x)$.

**Proof.** For the proof this this theorem, we show that the msets associated with the matrix $M$, is connected in the proper way to the matrices $A$, and $D$. It can be seen in the following proof, that the coefficients of the separate polynomials interlace in just the right way.

Let $M=\begin{bmatrix} A_{m \times m} & 0 \\ B & D_{n \times n} \end{bmatrix}$. Let $N=m+n$. For the matrix $M$, we know that

$p^+_M(x) = \bigoplus_{k=0}^{N} \sigma^{\text{par}(k)}_k x_{N-k}$, and $p^-_M(x) = \bigoplus_{k=0}^{N} \sigma^{\text{par}(k+1)}_k x_{N-k}$.

Recall that $\sigma_k(M)$ = “sum of all $k \times k$ principal minors of $M$”. The only non-zero entries are those which have part of the principal minor in $A$ and the rest of the principal minor is in $D$. Letting $\sigma_{\ell} = \sigma_{\ell}(A)$ and $\tau_{k-\ell} = \tau_{k-\ell}(D)$, we can write:

$$\sigma_k(M) = \biguplus_{\ell=0}^{k} (\sigma_{\ell} \boxtimes \tau_{k-\ell})$$

Each of the $\sigma_k(M)$ can be split into the even permutations and the odd permutations.

$$\sigma^e_k(M) = \biguplus_{\ell=0}^{k} (\sigma^e_{\ell} \tau^e_{k-\ell}) \boxplus \biguplus_{\ell=0}^{k} (\sigma^o_{\ell} \tau^o_{k-\ell})$$ \quad and \quad $$\sigma^o_k(M) = \biguplus_{\ell=0}^{k} (\sigma^o_{\ell} \tau^o_{k-\ell}) \boxplus \biguplus_{\ell=0}^{k} (\sigma^e_{\ell} \tau^e_{k-\ell})$$

Now consider the parts of the characteristic equations of the submatrices, $A$ and $D$.  

146
\[\begin{align*}
p_A^+(x) &= \sum_{k=0}^{m} \sigma_k^{\text{par}(k)} x^{m-k}, \quad \text{and} \quad p_A^-(x) = \sum_{k=0}^{m} \sigma_k^{\text{par}(k+1)} x^{m-k}, \\
p_D^+(x) &= \sum_{k=0}^{n} \sigma_k^{\text{par}(k)} x^{n-k}, \quad \text{and} \quad p_D^-(x) = \sum_{k=0}^{n} \sigma_k^{\text{par}(k+1)} x^{n-k}.
\end{align*}\]

Consider \(p_A^+(x)p_D^+(x) + p_A^-(x)p_D^-(x)\). 

\[\begin{align*}
p_A^+(x)p_D^+(x) &= \left(\sigma_0^0 x^m \oplus \sigma_1^0 x^{m-1} \oplus \sigma_2^0 x^{m-2} \oplus \sigma_3^0 x^{m-3} \oplus \cdots \oplus \sigma_m^0 x^0\right) \\
&\quad \otimes \left(\tau_0^n x^n \oplus \tau_1^n x^{n-1} \oplus \tau_2^n x^{n-2} \oplus \tau_3^n x^{n-3} \oplus \cdots \oplus \tau_n^n\right) \\
&= x^{m+n} \left(\sigma_0^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-1} \left(\sigma_0^0 \tau_1^n \oplus \sigma_1^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-2} \left(\sigma_0^0 \tau_2^n \oplus \sigma_1^0 \tau_1^n \oplus \sigma_2^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-3} \left(\sigma_0^0 \tau_3^n \oplus \sigma_1^0 \tau_2^n \oplus \sigma_2^0 \tau_1^n \oplus \sigma_3^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-4} \left(\sigma_0^0 \tau_4^n \oplus \sigma_1^0 \tau_3^n \oplus \sigma_2^0 \tau_2^n \oplus \sigma_3^0 \tau_1^n \oplus \sigma_4^0 \tau_0^n\right) \\
&\quad \oplus \cdots
\end{align*}\]

and

\[\begin{align*}
p_A^-(x)p_D^-(x) &= \left(\sigma_0^0 x^m \oplus \sigma_1^0 x^{m-1} \oplus \sigma_2^0 x^{m-2} \oplus \sigma_3^0 x^{m-3} \oplus \cdots \oplus \sigma_m^0 x^0\right) \\
&\quad \otimes \left(\tau_0^n x^n \oplus \tau_1^n x^{n-1} \oplus \tau_2^n x^{n-2} \oplus \tau_3^n x^{n-3} \oplus \cdots \oplus \tau_n^n\right) \\
&= x^{m+n} \left(\sigma_0^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-1} \left(\sigma_0^0 \tau_1^n \oplus \sigma_1^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-2} \left(\sigma_0^0 \tau_2^n \oplus \sigma_1^0 \tau_1^n \oplus \sigma_2^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-3} \left(\sigma_0^0 \tau_3^n \oplus \sigma_1^0 \tau_2^n \oplus \sigma_2^0 \tau_1^n \oplus \sigma_3^0 \tau_0^n\right) \\
&\quad \oplus x^{m+n-4} \left(\sigma_0^0 \tau_4^n \oplus \sigma_1^0 \tau_3^n \oplus \sigma_2^0 \tau_2^n \oplus \sigma_3^0 \tau_1^n \oplus \sigma_4^0 \tau_0^n\right) \\
&\quad \oplus \cdots
\end{align*}\]

So, adding the two previous results yields:
\[
p_A^+(x)p_D^+(x) \oplus p_A^-(x)p_D^-(x)
= x^{m+n} \left( \sigma_0^e \tau_0^e \oplus \sigma_0^o \tau_0^o \right)
\oplus x^{m+n-1} \left( \sigma_0^e \tau_1^e \oplus \sigma_0^o \tau_1^o \oplus \sigma_1^e \tau_0^e \right)
\oplus x^{m+n-2} \left( \sigma_0^e \tau_2^e \oplus \sigma_0^o \tau_2^o \oplus \sigma_2^e \tau_1^e \oplus \sigma_2^o \tau_1^o \right)
\oplus x^{m+n-3} \left( \sigma_0^e \tau_3^e \oplus \sigma_0^o \tau_3^o \oplus \sigma_3^e \tau_2^e \oplus \sigma_3^o \tau_2^o \right)
\oplus x^{m+n-4} \left( \sigma_0^e \tau_4^e \oplus \sigma_0^o \tau_4^o \oplus \sigma_4^e \tau_3^e \oplus \sigma_4^o \tau_3^o \right)
\oplus \ldots
\]

\[
= x^N \left( \sigma_0^e \tau_0^e \right) \oplus x^N \left( \sigma_0^o \tau_0^o \right)
\oplus x^{N-1} \left( \sigma_0^e \tau_1^e \oplus \sigma_0^o \tau_1^o \oplus \sigma_1^e \tau_0^e \right)
\oplus x^{N-2} \left( \sigma_0^e \tau_2^e \oplus \sigma_0^o \tau_2^o \oplus \sigma_2^e \tau_1^e \oplus \sigma_2^o \tau_1^o \right)
\oplus x^{N-3} \left( \sigma_0^e \tau_3^e \oplus \sigma_0^o \tau_3^o \oplus \sigma_3^e \tau_2^e \oplus \sigma_3^o \tau_2^o \right)
\oplus x^{N-4} \left( \sigma_0^e \tau_4^e \oplus \sigma_0^o \tau_4^o \oplus \sigma_4^e \tau_3^e \oplus \sigma_4^o \tau_3^o \right)
\oplus \ldots
\]

\[
= x^N \left( \sigma_0^e(M) \right) \oplus x^{N-1} \left( \sigma_1^e(M) \right)
\oplus x^{N-2} \left( \sigma_2^e(M) \right) \oplus x^{N-3} \left( \sigma_3^e(M) \right) \oplus x^{N-4} \left( \sigma_4^e(M) \right) \oplus \ldots
\]

Likewise, we can follow the same method to calculate \( p_A^-(x) \).
Consider \( p_A^+(x)p_D^+(x) \oplus p_A^-(x)p_D^-(x) \).

\[
p_A^+(x)p_D^+(x) = \left( \sigma_0^e x^m \oplus \sigma_0^o x^{m-1} \oplus \sigma_2^e x^{m-2} \oplus \sigma_2^o x^{m-3} \oplus \ldots \oplus \sigma_0^{ \text{par}(m)} \right)
\oplus \left( \tau_0^e x^n \oplus \tau_1^e x^{n-1} \oplus \tau_2^e x^{n-2} \oplus \tau_3^e x^{n-3} \oplus \ldots \oplus \tau_n^{ \text{par}(n+1)} \right)
\]

\[
= x^{m+n} \left( \sigma_0^e \tau_0^e \right)
\oplus x^{m+n-1} \left( \sigma_0^e \tau_1^e \oplus \sigma_1^e \tau_0^e \right)
\oplus x^{m+n-2} \left( \sigma_0^e \tau_2^e \oplus \sigma_2^e \tau_1^e \oplus \sigma_2^o \tau_0^e \right)
\oplus x^{m+n-3} \left( \sigma_0^e \tau_3^e \oplus \sigma_3^e \tau_2^e \oplus \sigma_3^o \tau_1^e \oplus \sigma_3^o \tau_0^e \right)
\oplus x^{m+n-4} \left( \sigma_0^e \tau_4^e \oplus \sigma_4^e \tau_3^e \oplus \sigma_4^o \tau_2^e \oplus \sigma_4^o \tau_1^e \oplus \sigma_4^o \tau_0^e \right)
\oplus \ldots
\]

and
\[ p_A(x)p_D^+(x) = \left( \sigma_0^0 x^m \oplus \sigma_1^0 x^{m-1} \oplus \sigma_2^0 x^{m-2} \oplus \sigma_3^0 x^{m-3} \oplus \cdots \oplus \sigma_m^{\text{par}(m+1)} \right) \]
\[ \oplus \left( \tau_0^0 x^n \oplus \tau_1^0 x^{n-1} \oplus \tau_2^0 x^{n-2} \oplus \tau_3^0 x^{n-3} \oplus \cdots \oplus \tau_n^{\text{par}(n)} \right) \]
\[ = x^{m+n} \left( \sigma_0^0 \tau_0^0 \right) \]
\[ \oplus x^{m+n-1} \left( \sigma_0^0 \tau_1^0 \oplus \sigma_1^0 \tau_0^0 \oplus \sigma_0^0 \tau_2^0 \oplus \sigma_2^0 \tau_1^0 \right) \]
\[ \oplus x^{m+n-2} \left( \sigma_0^0 \tau_2^0 \oplus \sigma_1^0 \tau_1^0 \oplus \sigma_2^0 \tau_0^0 \oplus \sigma_0^0 \tau_3^0 \oplus \sigma_3^0 \tau_1^0 \right) \]
\[ \oplus x^{m+n-3} \left( \sigma_0^0 \tau_3^0 \oplus \sigma_1^0 \tau_2^0 \oplus \sigma_2^0 \tau_1^0 \oplus \sigma_3^0 \tau_0^0 \right) \]
\[ \oplus x^{m+n-4} \left( \sigma_0^0 \tau_4^0 \oplus \sigma_1^0 \tau_3^0 \oplus \sigma_2^0 \tau_2^0 \oplus \sigma_3^0 \tau_1^0 \oplus \sigma_4^0 \tau_0^0 \right) \]
\[ \oplus \cdots \]

So, adding the two previous results yields:

\[ p_A(x)p_D^+(x) \oplus p_A(x)p_D^+(x) = x^{m+n} \left( \sigma_0^0 \tau_0^0 \oplus \sigma_0^0 \tau_0^0 \right) \]
\[ \oplus x^{N-1} \left( \sigma_0^0 \tau_1^0 \oplus \sigma_1^0 \tau_0^0 \right) \]
\[ \oplus x^{N-2} \left( \sigma_0^0 \tau_2^0 \oplus \sigma_1^0 \tau_1^0 \right) \]
\[ \oplus x^{N-3} \left( \sigma_0^0 \tau_3^0 \right) \]
\[ \oplus x^{N-4} \left( \sigma_0^0 \tau_4^0 \right) \]
\[ \oplus \cdots \]

The proof is complete. \qed

**Partitioned Matrices (Block Diagonal Matrix)**

**Theorem 9.33.** Let \( M = \begin{bmatrix} A & 0 \\ 0 & D \end{bmatrix} \). Let \( p_A(x) = p_A^+(x) \) be the characteristic equation for the submatrix A, and let \( p_D(x) = p_D^+(x) \) be the characteristic equation for the submatrix D. Then the
characteristic equation for $M$ is: $p_M^+(x) = p_M^-(x)$, where $p_M^+(x) = p_M^+(x)p_D^+(x) \oplus p_M^-(x)p_D^-(x)$, and $p_M^-(x) = p_M^+(x)p_D^+(x) \oplus p_M^+(x)p_D^-(x)$.

**Proof.** This is simply a corollary of Theorem 9.32.

**Note 9.34.** Recall that if $M$ were a matrix in $\mathbb{R}$, then the characteristic polynomial for $M$ is $\Delta_M = \Delta_A \Delta_D$. In the max-times algebra, we split each characteristic polynomial into the “positive part”, and the “negative part”. Write $\Delta_A = \Delta_A^+ - \Delta_A^-$, and $\Delta_D = \Delta_D^+ - \Delta_D^-$. Multiplying these together, and separating the parts again yields:

$$\Delta_M = \Delta_A \Delta_D = (\Delta_A^+ - \Delta_A^-)(\Delta_D^+ - \Delta_D^-) \quad \text{(344)}$$

$$= (\Delta_A^+ \Delta_D^- + \Delta_A^- \Delta_D^+) - (\Delta_A^+ \Delta_D^+ + \Delta_A^- \Delta_D^-) \quad \text{(345)}$$

$$= \Delta_A^+ \Delta_D^- - \Delta_A^- \Delta_D^+ \quad \text{(346)}$$

So $p_M^+(x) = p_A^+(x)p_D^+(x) \oplus p_A^-(x)p_D^-(x)$, and $p_M^-(x) = p_A^+(x)p_D^+(x) \oplus p_A^-(x)p_D^-(x)$.

A few examples are included to illustrate the method used above.

**Example 9.35.** Consider $M = \begin{bmatrix} 2 & 1 & 0 \\ 4 & 7 & 0 \\ 5 & 9 & 3 \end{bmatrix}$

For this example we have $A = \begin{bmatrix} 2 & 1 \\ 4 & 7 \end{bmatrix}$ and $D = \begin{bmatrix} 3 \end{bmatrix}$. The characteristic equation for $A$ is $x^2 \oplus 14 = 7x$, and for $D$, $x = 3$. Therefore, $p_A^+(x) = x^2 \oplus 14$, $p_A^- = 7x$, $p_D^+ = x$, and $p_D^- = 3$.

We now have:

$$p_M^+(x) = p_A^+(x)p_D^+(x) \oplus p_A^-(x)p_D^-(x) = x^3 \oplus 14x \oplus 21x = x^3 \oplus 21x$$

$$p_M^-(x) = p_A^+(x)p_D^+(x) \oplus p_A^-(x)p_D^-(x) = 7x^2 \oplus 3x^2 \oplus 42 = 7x^2 \oplus 42$$

This leads to the characteristic equation for $M$: $x^3 \oplus 21x = 7x^2 \oplus 42$, and it can be checked that:

$M^3 \oplus 21M = 7M^2 \oplus 42I$

We continue to the next example.

**Example 9.36.** Consider $M = \begin{bmatrix} 2 & 1 & 0 & 0 \\ 4 & 7 & 0 & 0 \\ 5 & 9 & 1 & 2 \\ 3 & 7 & 5 & 6 \end{bmatrix}$

For this example we have $A = \begin{bmatrix} 2 & 1 \\ 4 & 7 \end{bmatrix}$ and $D = \begin{bmatrix} 1 & 2 \\ 5 & 6 \end{bmatrix}$. The characteristic equation for $A$ is $x^2 \oplus 14 = 7x$, and for $D$, $x^2 = 6x \oplus 10$. Therefore, $p_A^+(x) = x^2 \oplus 14$, $p_A^- = 7x$, $p_D^+ = x^2$, and $p_D^- = 6x \oplus 10$.

150
We now have:

\[ p_M(x) = p_A^+ p_D^+ + p_A^- p_D^- = x^4 \boxplus 14x^2 \boxplus 42x^2 \boxplus 70x = x^4 \boxplus 42x^2 \boxplus 70x \]

\[ p_M(x) = p_A^+ p_D^+ + p_A^- p_D^- = 7x^3 \boxplus 6x^3 \boxplus 10x^2 \boxplus 84x \boxplus 140 = 7x^3 \boxplus 10x^2 \boxplus 84x \boxplus 140 \]

This leads to the characteristic equation:

\[ x^4 \boxplus 42x^2 \boxplus 70x = 7x^3 \boxplus 10x^2 \boxplus 84x \boxplus 140 \]

which can be simplified to:

\[ x^4 \boxplus 42x^2 = 7x^3 \boxplus 84x \boxplus 140. \]

And it can be checked that:

\[ M^4 \boxplus 42M^2 = 7M^3 \boxplus 84M \boxplus 140I. \]

And, finally, one more example:

\[
\begin{bmatrix}
9 & 3 & 4 & 1 \\
7 & 2 & 9 & 2 \\
4 & 7 & 6 & 0 \\
4 & 4 & 2 & 6 \\
2 & 7 & 8 & 3 \\
6 & 2 & 6 & 5
\end{bmatrix}
\]

**Example 9.37.** Consider \( M = \) 

For this example we have \( A = \begin{bmatrix} 9 & 3 & 4 & 1 \\ 7 & 2 & 9 & 2 \\ 4 & 7 & 6 & 0 \\ 4 & 4 & 2 & 6 \end{bmatrix} \) and \( D = \begin{bmatrix} 2 & 6 \\ 3 & 0 \end{bmatrix} \). The characteristic equation for

\[ A \text{ is } x^4 \boxplus 567x = 9x^3 \boxplus 63x^2 \boxplus 3402, \text{ and for } D, x^2 = 2x \boxplus 18. \]

Therefore, \( p_A^+(x) = x^4 \boxplus 567x, \)

\( p_A^{-} = 9x^3 \boxplus 63x^2 \boxplus 3402, \)

\( p_D^+ = x^2, \) and \( p_D^- = 2x \boxplus 18. \)

We now have:

\[ p_M^+(x) = p_A^+ p_D^+ + p_A^- p_D^- = x^6 \boxplus 567x^3 \boxplus 18x^4 \boxplus 126x^3 \boxplus 6804x \boxplus 162x^3 \boxplus 1134x^2 \boxplus 61236 \]

\[ = x^6 \boxplus 18x^4 \boxplus 567x^3 \boxplus 1134x^2 \boxplus 6804x \boxplus 61236 \]

\[ p_M^-(x) = p_A^+ p_D^- + p_A^- p_D^+ = 2x^5 \boxplus 18x^4 \boxplus 1134x^2 \boxplus 10206x \boxplus 9x^5 \boxplus 63x^4 \boxplus 3402x^2 \]

\[ = 9x^5 \boxplus 63x^4 \boxplus 3402x^2 \boxplus 10206x \]

This leads to the characteristic equation:

\[ x^6 \boxplus 18x^4 \boxplus 567x^3 \boxplus 1134x^2 \boxplus 6804x \boxplus 61236 = 9x^5 \boxplus 63x^4 \boxplus 3402x^2 \boxplus 10206x \]

which can be simplified to:

\[ x^6 \boxplus 567x^3 \boxplus 61236 = 9x^5 \boxplus 63x^4 \boxplus 3402x^2 \boxplus 10206x. \]

And it can be checked that:
Theorem 9.38. Let \( M = \begin{bmatrix} A_1 & 0 \\ A_2 & A_k \\ \vdots & \vdots \\ C & A_k \end{bmatrix} \)

The characteristic equation for \( M \) can be written as \( p_M^+ = p_M^- \), where:
\[
p_M^+ = \bigoplus (A_1^{(\pm)} A_2^{(\pm)} \cdots A_k^{(\pm)}) \text{, where the sum is taken over all parts such that the total number of negative parts is even (zero is an even number here), and}
\]
\[
p_M^- = \bigoplus (A_1^{(\pm)} A_2^{(\pm)} \cdots A_k^{(\pm)}) \text{, where the sum is taken over all parts such that the total number of negative parts is odd.}
\]

Proof. This can be proved easily by induction, using Theorem 9.32. \( \Box \)

Example:

If \( M = \begin{bmatrix} A & 0 \\ B & C \end{bmatrix} \), then the characteristic equation can be written as \( p_M^+ = p_M^- \), where
\[
\]
and
\[
\]

Bordered Matrices

Theorem 9.39. If \( M_{2 \times 2} = \begin{bmatrix} a & c \\ b^T & d \end{bmatrix} \), where \( a \) is a 1 \( \times \) 1 matrix and \( d \) is 1 \( \times \) 1, then the characteristic equation for \( M \) can be written as \( p_M^+ = p_M^- \), where
\[
p_M^+ = p_a^+ p_d^+ \quad \text{and} \quad p_M^- = p_a^- p_d^- \quad \text{and} \quad (b^T c)
\]

Proof. \( p_a^+ = x, p_a^- = a, p_d^+ = x, p_d^- = d. \)

Then \( p_M^+ = x^2 \oplus a d, \) and \( p_M^- = (a \oplus b) x \oplus b c \) \( \Box \)

The following facts are well-known from linear algebra.

Fact 9.40. \[ \begin{bmatrix} A & y \\ x^T & z \end{bmatrix} = \det(A) \ d - x^T \ \text{adj}(A) \ y. \]
Fact 9.41.

\[ \text{adj}(\lambda I - A) = \sum_{k=0}^{n-1} A_k \lambda^k \]  

(347)

where \( A_k = a_{k+1}I + a_{k+2}A + \cdots + a_n A^{n-(k+1)} \). The \( a_k \)'s are defined by:

\[ a_{k+1} = (-1)^{n-(k+1)} \sigma_{n-(k+1)} \], where the \( \sigma_k \)'s are the coefficients of the characteristic polynomial.

Example 9.42. Consider the \( 2 \times 2 \) matrix \( A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \in \mathbb{R}^{2 \times 2} \).

The characteristic polynomial of \( A \) is \( \lambda^2 - (a_{11} + a_{22})\lambda + (a_{11}a_{22} - a_{12}a_{21}) \)

Here, \( \sigma_0 = 1, \ \sigma_1 = (a_{11} + a_{22}), \ \sigma_2 = (a_{11}a_{22} - a_{12}a_{21}) \)

So

\[ a_0 = (-1)^2 \sigma_2 = (a_{11}a_{22} - a_{12}a_{21}), \]
\[ a_1 = (-1)^1 \sigma_1 = -(a_{11} + a_{22}), \ \text{and} \]
\[ a_2 = (-1)^0 \sigma_0 = 1. \]

\[ A_0 = a_1 I + a_2 A = \begin{bmatrix} -a_{11} - a_{22} & 0 \\ 0 & -a_{11} - a_{22} \end{bmatrix} + \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} -a_{22} & a_{12} \\ a_{21} & -a_{11} \end{bmatrix} \]

\[ A_1 = a_2 I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \]

\[ \text{adj}(\lambda I - A) = A_0 + A_1 \lambda = \begin{bmatrix} -a_{22} & a_{12} \\ a_{21} & -a_{11} \end{bmatrix} + \begin{bmatrix} \lambda & 0 \\ 0 & \lambda \end{bmatrix} = \begin{bmatrix} \lambda - a_{22} & a_{12} \\ a_{21} & \lambda - a_{11} \end{bmatrix} \]

Theorem 9.43. If \( M_{3 \times 3} = \begin{bmatrix} A \\ b^T \\ d \end{bmatrix} \), where \( A \) is a \( 2 \times 2 \) matrix and \( d \) is a scalar, then the characteristic equation for \( M \) can be written as \( p_M^+ = p_M^- \), where

\[ p_M^+ = p_A^+ p_d^+ \boxplus p_A^- p_d^- \boxplus (a_1 \boxplus a_2)(b^T c) \],

and

\[ p_M^- = p_A^+ p_d^+ \boxplus p_A^- p_d^- \boxplus (b^T c) x \boxplus (b^T A c) \]

Proof. The proof of this theorem is based on the determinant of a bordered matrix as given in

Lemma 9.40. Consider the matrix \( M = \begin{bmatrix} a_{11} & a_{12} & c_1 \\ a_{21} & a_{22} & c_2 \\ b_1 & b_2 & d \end{bmatrix} \)

We calculate the \( \det(\lambda I - M) \), just as in the conventional algebra.

153
\[
\det(\lambda I - M) = \begin{vmatrix}
\lambda I - A & -c \\
-b^T & \lambda - d
\end{vmatrix}
= \det(\lambda I - A) \cdot (\lambda - d) - b^T \text{adj}(\lambda I - A)c
\]

From Example 9.42, we have that \(\text{adj}(\lambda I - A) = a_1 I + a_2 A + a_2 I \lambda\)

This leads to the equation

\[
\text{adj}(\lambda I - M) = \det(\lambda I - A) \cdot (\lambda - d) - b^T \text{adj}(\lambda I - A)c
= \det(\lambda I - A) \cdot (\lambda - d) - b^T (a_1 I + a_2 A + a_2 I \lambda)c
= \det(\lambda I - A) \cdot (\lambda - d) - a_1 b^T c - a_2 b^T A c - a_2 b^T c \lambda
= \det(\lambda I - A) \cdot (\lambda - d) + (a_{11} + a_{22}) b^T c - b^T A c - b^T c \lambda
\]

Setting the above equation equal to zero and moving all negative terms to the other side of the equation leads to the equation given in the theorem.

An alternative method to calculate the equation using the methods of section 10 is:

\((p^+, p^-) \oplus (\lambda, d) \oplus (a_{11} \boxplus a_{22}) b^T c, 0) \oplus (0, b^T A c) \oplus (0, b^T c \lambda)\).

\[\blacksquare\]

**Note 9.44.** Although this algorithm could be generalized to larger \(n \times n\) bordered matrices with \(n > 3\), the results get increasingly more complicated because the \(a_8\)s have to be split into \(a_i^+\) and \(a_i^-\); and no savings are realized over the algorithm given in section 9.1.

**Example 9.45.** Consider \(M = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}\)

If this case we have:

\[
\begin{align*}
\lambda x &= 1 \\
\lambda x &= 4
\end{align*}
\]

\[
x^2 \boxplus 4 = 4x \boxplus x
\]

\(b^T c = 6\).

This yields \(x^2 \boxplus 4 = 4x \boxplus x \boxplus 6\). This can be simplified to \(x^2 = 4x \boxplus 6\), and it can be checked that \(M\) satisfies the equation \(M^2 = 4M \boxplus 6I\).
Partitioned Matrices and Recursion

The above sections lead to a recursive method to find the polynomial equation associated with some particular matrices.

**Example 9.46.** Consider \( M = \begin{bmatrix} 0 & 0 & 2 & 0 \\ 2 & 2 & 0 & 0 \\ 3 & 3 & 3 & 0 \\ 3 & 3 & 3 & 1 \end{bmatrix} \)

To calculate the characteristic equation for this polynomial, we start from the \( 1 \times 1 \) principal submatrix, and continue with the next larger principal submatrix. We can use recursion (updates) on this \( 4 \times 4 \) matrix because it is reducible and thus no \( 4 \times 4 \) updates are necessary as noted in Note 9.44.

(a) \( [0] \quad x = 0 \)

(b) \[
\begin{bmatrix}
0 & 0 \\
2 & 2 \\
\end{bmatrix}
\]

\[
\begin{align*}
x &= 0 \\
x &= 2 \\
x^2 \equiv 0 &= 2x \equiv 0 \\
x^2 &= 2x
\end{align*}
\]

(c) \[
\begin{bmatrix}
0 & 0 & 2 \\
2 & 2 & 0 \\
3 & 3 & 3 \\
\end{bmatrix}
\]

\[
\begin{align*}
x^2 &= 2x \\
x &= 3 \\
x^3 \equiv 6x &= 3x^2 \equiv 2x^2 \\
x^3 \equiv 6x &= 3x^2
\end{align*}
\]

\( b^T c = \begin{bmatrix} 3 & 3 \end{bmatrix} \begin{bmatrix} 2 \\ 0 \end{bmatrix} = 6 \)

\( (a_{11} \oplus a_{22}) b^T c = (2)(6) = 12 \)

\( b^T A c = \begin{bmatrix} 3 & 3 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} 2 \\ 0 \end{bmatrix} = 12 \)

\[
\begin{align*}
x^3 \equiv 6x \equiv 12 &= 3x^2 \equiv 6x \equiv 12 \\
x^3 &= 3x^2
\end{align*}
\]

(d) \[
\begin{bmatrix}
0 & 0 & 2 & 0 \\
2 & 2 & 0 & 0 \\
3 & 3 & 3 & 0 \\
3 & 3 & 3 & 1 \\
\end{bmatrix}
\]

\[
\begin{align*}
x^3 &= 3x^2 \\
x &= 1 \\
x^4 \equiv 3x^2 &= x^3 \equiv 3x^2 \\
x^4 \equiv 3x^2 &= x^3 \equiv 3x^2
\end{align*}
\]

So in this example, we find the characteristic polynomial for the matrix \( A \) to be \( x^4 \equiv 3x^2 = 3x^3 \), which agrees with the Algorithm 9.1.
10 Algebra of Polynomial Pairs in the Max-Times Algebra

10.1 Evaluation Mapping

Definition 10.1 (Evaluation Mapping for elements of $R$).
If $\alpha \in R$, and $p \in R[x]$, then $F_{\alpha}(p) = \"p(\alpha)\" = p_0 + p_1\alpha + \cdots + p_n\alpha^n$

For the two specific algebras, we have:

(i) $[[\text{Max},\times]], p(\alpha) = \max_{0 \leq k \leq n} \{ p_k\alpha^k \}$

(ii) $[3^n], p(\alpha) = \sum_{k=0}^{n} p_k\alpha^k$

Proposition 10.2.
1. $F_{\alpha}$ is linear: $F_{\alpha}(p \oplus q) = F_{\alpha}(p) + F_{\alpha}(q)$

2. $F_{\alpha}(\beta \otimes p \oplus q) = \beta \times F_{\alpha}(p) + F_{\alpha}(q)$

Definition 10.3 (Evaluation Mapping for Matrices over $R^{n \times n}$).
Let $A \in R_{n \times n}, p \in R[x]$, then
$\phi_A(p) = \"p(A)\" = p_0 \times I + p_1 \times A + \cdots + p_n \times A^n$

Proposition 10.4. $\phi_A$ is linear: $\phi_A(\beta q \oplus p) = \beta \times \phi_A(p) + \phi_A(q)$

Proposition 10.5. $\phi_A$ is multiplicative. I.e. $\phi_A(p \oplus q) = \phi_A(p) \times \phi_A(q)$.

The proof of the two propositions above are identical to the proof over rings.

Definition 10.6. In $R[x]$, we say that $f = g$ if and only if $F_x(f) = F_x(g)$ for all $x \in R^+$

Note 10.7. In this respect, we say that two polynomials are equal if their valuations are equal.

We are considering, here, the polynomials as polynomial functions and not as polynomial forms

which are ordered sequences of coefficients.

(Max, $\times$)-Algebra

Theorem 10.8. $(x \oplus a)^k = x^k \oplus a^k$, for all $a \in R^+$, and for all $k \in \mathbb{N}$

Proof. First, we note that if $x = a$ then the theorem is obvious since $\oplus$ is an idempotent operation.

We prove this lemma by induction on $k$. For $k = 1$, the result is obvious. Suppose that the lemma is true for $k$, we now show that it is true for $n = k+1$.

$$
(x \oplus a)^{k+1} = (x \oplus a) \oplus (x \oplus a)^k
$$

$$
= (x \oplus a) \oplus (x^k \oplus a^k)
$$

$$
= x^{k+1} \oplus ax^k \oplus a^k x \oplus a^{k+1}
$$
If \( x < a \), then \( ax^k < a^{k+1} \), and \( a^k x < a^{k+1} \),
and if \( x > a \) then \( ax^k < x^{k+1} \), and \( a^k x < x^{k+1} \).
Therefore, \((x \boxplus a)^{k+1} = x^{k+1} \boxplus a^{k+1}\)

In \( \mathbb{R} \), we know that if two polynomials are equal as evaluations, then they are also equal as formal polynomials. This may be stated as saying there is a bijection between polynomials as valuations and formal polynomials. In the max-times algebra this is not the case, although \((\text{Max}, \times)\) is an infinite semiring.

**Example 10.9.** \((x \boxplus 2)^2 = x^2 \boxplus 2x \boxplus 2x \boxplus 4 = x^2 \boxplus 2x \boxplus 4 = x^2 \boxplus 4\)

In this example the term “2x” is dominated by the other two terms for any nonnegative real number.

What can be said about two polynomials which are equal, as evaluations?

**Lemma 10.10.** If \( f(x), g(x) \in \mathbb{R}[x] \), and \( f(x) = g(x) \) (as evaluations), then

1. \( \partial f(x) = \partial g(x) \) (degree of \( f(x) \) = degree of \( g(x) \)).
2. the leading coefficients of the two polynomials are equal.
3. the constant terms of the two polynomials are equal.

i.e. if \( f(x) = \max_k \{ a_k x^k \mid k = 0, 1, \ldots, n \} \), and \( g(x) = \max_\ell \{ b_\ell x^\ell \mid \ell = 0, 1, \ldots, m \} \), then

1. \( m=n \)
2. \( a_n = b_m \)
3. \( a_0 = b_0 \)

**Proof.** Suppose \( f(x) = \max_k \{ a_k x^k \mid k = 0, 1, \ldots, n \} \), and \( g(x) = \max_\ell \{ b_\ell x^\ell \mid \ell = 0, 1, \ldots, m \} \), with \( a_n \neq 0 \) and \( b_m \neq 0 \).

Suppose that \( n > m \), then we have

\( a_n x^n \boxplus (\text{other stuff}) = b_m x^m \boxplus (\text{lower powers}) \).

If \( x \) is sufficiently large then \( a_n x^n > b_m x^m \boxplus (\text{lower orders}) \).

If \( a_n \neq 1 \), then divide both sides by \( a_n \).

\[
x^n > b_i x^i \quad \text{for all} \ 0 \leq i \leq m
\]
\[
x^{n-i} > b_i
\]
\[
x > \sqrt[n]{b_i}
\]
\[
X_0 = \max_{i=0,1,\ldots,m} \{ \sqrt[n]{b_i} \}
\]
For \( x > X_0 \), \( a_n x^n > b_m x^m \iff b_{m-1} x^{m-1} \iff \cdots \iff b_0 \), which can’t happen. Therefore \( \partial p(x) = \partial q(x) \). Likewise, since we have shown that the degree of the two polynomials are equal, we can use the same reasoning to show that the leading coefficients of the two polynomials must also be equal. Since the two polynomials evaluate identically for all \( x \in \mathbb{R}^+ \), then, in particular, 

\[
a_0 = f(0) = g(0) = b_0.
\]

\( \square \)

We would like to develop a method similar to the Euclidean Algorithm for the polynomials in 

\( (\text{Max} \times x) \). The following example shows that this is futile.

**Example 10.11.** Consider the two polynomials, \((x^2 \oplus 1)\), and \((x \oplus 1)\). Can we write this as 

\[
(x^2 \oplus 1) = q \oplus (x \oplus 1) \oplus r, \text{ with } \partial r < \partial (x \oplus 1)?
\]

Here we must have \( \partial q = 1 \), and \( \partial r = 0 \). Therefore we may write this equation as

\[
x^2 \oplus 1 = (q_1 x \oplus q_0) \oplus (x \oplus 1) \oplus r_0.
\]

\[
x^2 \oplus 1 = q_1 x^2 \oplus q_1 x \oplus q_0 x \oplus q_0 \oplus r_0
\]

Comparing the left and right sides of the above equation, we see that \( q_1 \) must equal 1, and \( q_0 \) must be less than 1. If this is the case, then the right side of the equation above becomes 

\[
x^2 \oplus x \oplus q_0 \oplus r. \text{ This can not equal the left side of the equation. Therefore, we can not write}
\]

\[
(x^2 \oplus 1) = q \oplus (x \oplus 1) \oplus r, \text{ with } \partial r < \partial (x \oplus 1)
\]

Although Example 10.11 shows that we cannot, in general, develop a division algorithm in 

\( (\text{Max} \times x) \) which is similar to the Euclidean Algorithm, the following example shows that, for certain polynomials we can write an equation which is similar to the result of the Euclidean Algorithm.

**Example 10.12.** Consider the two polynomials, \((x^2 \oplus 2x \oplus 3)\), and \((x \oplus 1)\). Can we write this as 

\[
(x^2 \oplus 2x \oplus 1) = q \oplus (x \oplus 1) \oplus r, \text{ with } \partial r < \partial (x \oplus 1)?
\]

Here, we can write the appropriate equation

\[
(x^2 \oplus 2x \oplus 3) \equiv (x \oplus 2) \oplus (x \oplus 1) \oplus 3
\]

### 10.2 Equations in \((\mathbb{R}[x], \oplus, \oplus)\)

In the previous section we have considered polynomials in \(\mathbb{R}[x]\). In this section we investigate equations in \(\mathbb{R}[x]\). An equation is a relationship between two polynomials in \(\mathbb{R}[x]\), i.e. \( p(x) = q(x) \), with \( p(x), q(x) \in \mathbb{R}[x] \). A "solution", or the "solution set", to an equation is the set of all elements, \( a \in \mathbb{R} \), such that \( p(a) = q(a) \).

Consider the equation, in the unknown variable \(x\), in \(\mathbb{R}[x]\), \( p(x) = q(x) \). We are interested in the solution(s) to such equations. We note that not all equations have solutions. For example, 

\( x \oplus 4 = 2 \) has no solutions in the \((\text{Max}, \times \) - algebra. 

158
Example 10.13 \((\text{Max}, \times)\). \(x \boxplus 4 = 2\) has no solutions.

Example 10.14 \((\text{Max}, \times)\). \(x \boxplus 2 = 4\) has \(x=4\) as the only solution.

Example 10.15 \((\text{Max}, \times)\). \(x \boxplus 2 = x \boxplus 1\) has the solution set \(\{x \mid x \geq 2\}\)

Equivalence of equations

Definition 10.16. Given two polynomial equations, \(p_1(x)=p_2(x)\), and \(q_1(x)=q_2(x)\), we say that the two polynomials are equivalent, denoted \(p_1=p_2 \sim q_1=q_2\), if the two equations have the same solution set.

Lemma 10.17. Definition 10.16 is an equivalence relation.

Proof. It is easy to see that the relation is Reflexive, Symmetric, and Transitive, since the sets associated with the equations are equal in the set-theoretical sense, i.e. the sets associated with each equation are equal.

It is interesting to note that if \(p(x)\) has terms dominated by all other terms in the polynomial, then the terms can be dropped. Example: \(x^2 \boxplus 2x \boxplus 4\) can be replaced by \(x^2 \boxplus 4\), since the term “\(2x\)” is dominated by the other two terms for any number in \((\text{Max}, \times)\). This is not true, however, for matrices. Consider the two equations from above, and the matrix \(A=\begin{bmatrix} 1 & 7 \\ 4 & 1 \end{bmatrix}\).

For this matrix, we have:
\[
A^2 \boxplus 2A \boxplus 4I = \begin{bmatrix} 28 & 7 \\ 4 & 28 \end{bmatrix} \boxplus \begin{bmatrix} 2 & 14 \\ 8 & 2 \end{bmatrix} \boxplus \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} = \begin{bmatrix} 28 & 14 \\ 8 & 28 \end{bmatrix}
\]

while
\[
A^2 \boxplus 4I = \begin{bmatrix} 28 & 7 \\ 4 & 28 \end{bmatrix} \boxplus \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} = \begin{bmatrix} 28 & 7 \\ 4 & 28 \end{bmatrix}
\]

Therefore, for this matrix, \(A^2 \boxplus 2A \boxplus 4I \neq A^2 \boxplus 4I\).

10.3 \((\mathbb{P}^2, \oplus, \otimes)\)

Let \(\mathbb{P}^2 = \mathbb{R}[x] \times \mathbb{R}[x]\).

In the previous section we considered solution sets for equations in the \((\mathbb{R}[x], \boxplus, \otimes)\) semiring. Let us look closer at these equations. To facilitate our investigation, we will consider polynomial equations as a pair of polynomials.

An equation \(p_1(x)=p_2(x)\) can be associated with an ordered pair \((p_1, p_2)\). For reasons which will be apparent later, we will write the equations as \(p^+(x)=p^-(x)\) and the ordered pairs as \((p^+, p^-)\).

Let us define an algebra on these ordered pairs.

Definition 10.18.
(1) For $\alpha \in \mathbb{R}$, $\alpha \odot (p^+, p^-) = (\alpha p^+, \alpha p^-)$.

(2) For $f(x) \in \mathbb{R}[x]$, $f(x) \odot (p^+, p^-) = (f(x) \boxplus p^+, f(x) \boxplus p^-)$.

(3) Let $p = (p^+, p^-)$, $q = (q^+, q^-) \in \mathbb{P}^2$. Then

(a) $p \oplus q = (p^+, p^-) \oplus (q^+, q^-) \equiv (p^+ \boxplus q^+, p^- \boxplus q^-)$

(b) $p \otimes q = (p^+, p^-) \otimes (q^+, q^-) \equiv (p^+q^+ \boxplus p^-q^-, p^+q^- \boxplus p^-q^+)$

**Theorem 10.19.** The system $(\mathbb{P}^2, \oplus, \otimes)$ is an idempotent semiring.

**Proof.** We go through the proof in detail. We write $p, q \in \mathbb{R}[x]$ instead of $p(x), q(x)$.

(A) $\oplus$

(1) Closure:

$p \oplus q = (p^+, p^-) \oplus (q^+, q^-) = (p^+ \boxplus q^+, p^- \boxplus q^-)$

$p^+ \boxplus q^+ \in \mathbb{P}$, and

$p^- \boxplus q^- \in \mathbb{P}$. Therefore, $p \oplus q \in \mathbb{P}^2$.

(2) Associativity:

$[p \oplus q] \oplus r = [(p^+, p^-) \oplus (q^+, q^-)] \oplus (r^+, r^-)$

$= (p^+ \boxplus q^+, p^- \boxplus q^-) \oplus (r^+, r^-)$

$= ((p^+ \boxplus q^+) \boxplus r^+, (p^- \boxplus q^-) \boxplus r^-)$

$= (p^+ \boxplus (q^+ \boxplus r^+), p^- \boxplus (q^- \boxplus r^-))$

$= (p^+, p^-) \oplus ((q^+ \boxplus r^+, q^- \boxplus r^-))$

$= (p^+, p^-) \oplus [(q^+, q^-) \oplus (r^+, r^-)]$

$= p \oplus [q \oplus r]$

(3) Commutativity: ($\oplus$ is commutative because $\boxplus$ is commutative.)

$p \oplus q = (p^+, p^-) \oplus (q^+, q^-)$

$= (p^+ \boxplus q^+, p^- \boxplus q^-)$

$= (q^+ \boxplus p^+, q^- \boxplus p^-)$

$= (q^+, q^-) \oplus (p^+, p^-)$

$= q \oplus p$

(4) Additive identity:

$(0, 0)$ is the additive identity of $\mathbb{P}^2$.

$(0, 0) \oplus p = (0, 0) \oplus (p^+, p^-) = (p^+, p^-) \oplus (0, 0) = (p^+, p^-) = p$
(B) ⊗

(a) Closure:

\[ p \otimes q = (p^+, p^-) \otimes (q^+, q^-) = (p^+q^+ \boxplus p^-q^-, p^+q^- \boxplus p^-q^+) \text{.} \]

\[ p^+ \boxplus q^+ \boxplus p^- \boxplus q^- \in R[x] \text{, and} \]

\[ p^+ \boxplus q^- \boxplus p^- \boxplus q^+ \in R[x] \]

Therefore \( p \otimes q \in \mathbb{P}^2 \).

(b) Associativity:

\[
[p \otimes q] \otimes r = [(p^+, p^-) \otimes (q^+, q^-)] \otimes (r^+, r^-)
= [(p^+q^+ \boxplus p^-q^-, p^+q^- \boxplus p^-q^+) \otimes (r^+, r^-)]
= ((p^+q^+ \boxplus p^-q^-)r^+ \boxplus (p^+q^- \boxplus p^-q^+)r^-)
\]

\[
= (p^+q^+r^+ \boxplus p^-q^-r^+ \boxplus p^+q^-r^- \boxplus p^-q^+r^-)
\]

\[
= (p^+q^+r^+ \boxplus p^-q^-r^- \boxplus p^+q^-r^- \boxplus p^-q^+r^-)
\]

\[
= (p^+q^+r^+ \boxplus p^-q^-r^- \boxplus p^+q^-r^- \boxplus p^-q^+r^-)
\]

\[
= (p^+q^+r^+ \boxplus p^-q^-r^- \boxplus p^+q^-r^- \boxplus p^-q^+r^-)
\]

\[
= q \otimes (q^+, q^-) \otimes (q^+, q^-)
\]

(c) Commutativity:

\[ p \otimes q = (p^+, p^-) \otimes (q^+, q^-) \]

\[ = (q^+p^+ \boxplus q^-p^-, q^+p^- \boxplus q^-p^+) \]

\[ = q \otimes p \]

(d) Multiplicative Identity:

\( (1,0) \) is the multiplicative identity.

\[ (1,0) \otimes p = (1,0) \otimes (p^+, p^-) = (1 p^+ \boxplus 0 p^- , 0 p^- \boxplus 1 p^-) = (p^+, p^-) = p. \]

(e) Absorbing Property of Additive Identity:

\[ (0,0) \otimes p = (0,0) \otimes (p^+, p^-) = (0,0). \]

\[ p \otimes (0,0) = (p^+, p^-) \otimes (0,0) = (0,0). \]

(C) Distributivity of \( \otimes \) over \( \oplus \).
We show left distributivity, and leave right distributivity for the reader.

\[
p \otimes [q \oplus r] = (p^+, p^-) \otimes [(q^+, q^-) \oplus (r^+, r^-)]
\]

\[
= (p^+, p^-) \otimes [q^+ \boxplus r^+, q^- \boxoplus r^-]
\]

\[
= (p^+ q^+ \boxplus p^+ r^+, p^- q^- \boxoplus p^- r^-)
\]

And the proof is complete. \(\square\)

We can add the following lemma.

**Lemma 10.20.** If \(R[x]\) is idempotent, then \(\mathbb{P}^2\) is idempotent.

**Proof.** \(p \oplus p = (p^+, p^-) \oplus (p^+, p^-) = (p^+ \boxplus p^+, p^- \boxoplus p^-) = (p^+, p^-) = p\) \(\square\)

**Equivalence of polynomial pairs**

**Definition 10.21.** \((p^+, p^-)\) is said to be equivalent to \((q^+, q^-)\) if and only if \(p^+(x) = p^-(x)\) is equivalent to \(q^+(x) = q^-(x)\) as equations from section 10.2.

We note here that if \(p_1(x) = p_2(x) \sim q_1(x) = q_2(x)\) and \(a \in R\) with \(p_1(a) = p_2(a)\), then \(q_1(a) = q_2(a)\). However, this is not true for matrices. As an example, consider the equivalence of the equations: \(x^2 = 2x \boxplus 3 \sim x = 2\). They are equivalent since both equations have \(x = 2\) as the only solution. If we consider the matrix \(A = \begin{bmatrix} 2 & 3 \\ 1 & 1 \end{bmatrix}\), we note that \(p_1(A) = p_2(A)\) but \(q_1(A) \neq p_2(A)\). So, \(A^2 = 2A \boxplus 3I\), but \(A \neq 2I\).

Another counterexample: \(x^2 = 2x \boxplus 3 \sim x^2 = 2x \boxoplus 1\). The matrix \(A\) above satisfies the equation \(x^2 = 2x \boxplus 3\), but matrix \(A\) above does not satisfy the equation \(x^2 = 2x \boxoplus 1\).

**Division**

Our main motivation for considering division of polynomial pairs is to work with the Characteristic Polynomials associated with matrices. As such, we will assume, in the polynomial equation \(p^+(x) = p^-(x)\), that \(\partial p^+ > \partial p^-\)

We define a division for these polynomial pairs. Suppose that \(\partial p^+ > \partial p^-\), and \(\partial h^+ > \partial h^-\).
**Definition 10.22.**

We say that \( p \mid h \) (as polynomial pairs) if there exists a polynomial pair, \( q, \in \mathbb{P}^2 \), such that
\[ p \otimes q = h, \]
or
\( (p^+, p^-) \mid (h^+, h^-) \) if there exists \((q^+, q^-) \in \mathbb{P}^2 \), such that \( (p^+, p^-) \otimes (q^+, q^-) = (h^+, h^-) \).

The definition above can be written as:
\[
\begin{align*}
  h^+ &= \gamma^+ h^+ \boxplus \gamma^- h^- & (348) \\
  h^- &= \gamma^- h^+ \boxplus \gamma^+ h^- & (349)
\end{align*}
\]

Let us show that this (division) is a Reflexive, Transitive, Anti-symmetric relation on \( \mathbb{P}^2 \). We assume that all equations in this section represent “identities”, equations which are true for all \( x \in R \).

(A) Reflexive:
\[ p \mid p, \text{ since } (1,0) \otimes p = p. \]

(B) Transitive:
Suppose \( p \mid q \), and \( q \mid h \).
Then there exists an \( \alpha \) such that \( \alpha \otimes p = q \), and there exists a \( \beta \) such that \( \beta \otimes q = h \).
Then \( h = \beta \otimes q = \beta \otimes [\alpha \otimes p] = [\beta \otimes \alpha] \otimes p \). Therefore \( p \mid h \).

(C) Anti-Symmetric:
Suppose \( p \mid h \) and \( h \mid p \). Then \( h=\alpha \otimes p \), and \( p=\beta \otimes h \). Then
\[ h=\alpha \otimes [\beta \otimes h] = [\alpha \otimes \beta] \otimes h = \gamma \otimes h, \text{ where } \gamma = [\alpha \otimes \beta]. \] This leads to:
\[
\begin{align*}
  h^+ &= \gamma^+ h^+ \boxplus \gamma^- h^- & (350) \\
  h^- &= \gamma^- h^+ \boxplus \gamma^+ h^- & (351)
\end{align*}
\]

By using Lemma 10.10, we get that \( \gamma^+ = 1 \) from Equation (350), and \( \gamma^- = 0 \) from Equation (351). Therefore \( \gamma = (1,0) \), which implies that \( \alpha \otimes \beta = (1,0) \).
\[
\begin{align*}
  \gamma &= (1,0) \\
  \alpha \otimes \beta &= (1,0) \\
  (\alpha^+, \alpha^-) \otimes (\beta^+, \beta^-) &= (1,0) \\
  (\alpha^+ \beta^+ \boxplus \alpha^- \beta^-, \alpha^+ \beta^- \boxplus \alpha^- \beta^+) &= (1,0)
\end{align*}
\]

\[
\begin{align*}
  \alpha^+ \beta^+ \boxplus \alpha^- \beta^- &= 1 \\
  \alpha^+ \beta^- \boxplus \alpha^- \beta^+ &= 0 & (352)
\end{align*}
\]

Equation (352) leads to the following two cases:
(I) $\alpha^+ \beta^+ \neq 0$

$\alpha^+ \beta^+ \neq 0 \implies \alpha^+ \neq 0 \text{ and } \beta^+ \neq 0$

$\implies \beta^- = 0 \text{ and } \alpha^- = 0 \text{ since } \alpha^+ \beta^- = 0 \text{ and } \alpha^- \beta^+ = 0$

$\implies \alpha^+ \beta^+ = 1$

$\implies \alpha^+ \text{, and } \beta^+ \text{ are constants by definition (of degree)}$

$\implies (h^+, h^-) = (\alpha^+, 0) \odot (p^+, p^-) = \alpha^+ \odot (p^+, p^-)$

$\implies h = \alpha \odot p, \text{ where } \alpha \text{ is a constant}.$

(II) $\alpha^- \beta^- \neq 0$

$\alpha^- \beta^- \neq 0 \implies \alpha^- \neq 0 \text{ and } \beta^- \neq 0$

$\implies \beta^+ = 0 \text{ and } \alpha^+ = 0$

$\implies \alpha^- \beta^- = 1$

$\implies \alpha^-, \text{ and } \beta^- \text{ are constants by definition (of degree)}$

$\implies (p^+, p^-) = (0, \beta^-) \odot (h^+, h^-) = \beta^- \odot (h^+, h^-)$

$\implies p = \beta \odot h, \text{ where } \beta \text{ is a constant}.$

$$\begin{align*}
\begin{cases}
h^+ = \alpha p^+ \\
h^- = \alpha p^-
\end{cases}
\text{ or } \begin{cases}
p^+ = \beta h^- \\
p^- = \beta h^+
\end{cases}
\end{align*}$$

(353)

Since this division relation has been shown to be Reflexive, Transitive, and Anti-Symmetric, it induces a partial order on the system $(\mathbb{P}^2, \odot, \otimes): p \leq q \iff p \mid q$

**Note 10.23.**

1. $(1,0) \odot (p^+, p^-) = (p^+, p^-)$
2. $(0,1) \odot (p^+, p^-) = (p^-, p^+)$
3. We can define: $e = (1,0), \text{ and } i = (0,1)$, then

   a. $i^2 = e$
   b. $(p^+, p^-) = [p^+ \odot e] \odot [p^- \odot i]$
   c. $(p^+, p^-) \odot (q^+, q^-) = [p^+ \odot (q^+, q^-)] \odot [p^- \odot (0,1) \odot (q^+, q^-)]$
10.4 Ideal

**Definition 10.24.** Given a matrix $A$, define

$$\eta_A \equiv \{ \ p = (p^+, p^-) \in \mathbb{P}^2 \mid p^+(A) = p^-(A), \text{ and } \partial p^+ > \partial p^- \}$$

From Section 8.9 we know that $\eta_A \neq \emptyset$ since the Characteristic Polynomial Equation Pair associated with the matrix $A$ exists and is an element of $\eta_A$.

**Lemma 10.25.** If $p \in \eta_A$, and $\alpha \in \mathbb{R}$, then $\alpha p \in \eta_A$.

**Proof.** The proof of this lemma follows from the fact that multiplication by a constant is calculated element-wise.

**Lemma 10.26.** If $p \in \eta_A$, and $f \in \mathbb{R}[x]$, then $(f \odot p) \in \eta_A$.

**Proof.** Suppose $p^+(A) = p^-(A)$. Consider $f(A)p^+(A)$, and $f(A)p^-(A)$.

$$\begin{bmatrix} \cdots & \cdots & \cdots \\ \vdots & \vdots & \vdots \\ \cdots & \cdots & \cdots \end{bmatrix} \odot \begin{bmatrix} \vdots \\ \vdots \\ \vdots \end{bmatrix} = \begin{bmatrix} \cdots & \cdots & \cdots \\ \vdots & \vdots & \vdots \\ \cdots & \cdots & \cdots \end{bmatrix} \odot \begin{bmatrix} \vdots \\ \vdots \\ \vdots \end{bmatrix}$$

(354)

Look at the $i^\text{th}$ element of the product. Since $p^+(A) = p^-(A)$ then $[p^+(A)]_{i\bar{j}} = [p^-(A)]_{i\bar{j}} \forall 1 \leq i, j \leq n$, then $[f(A) p^+(A)]_{i\bar{j}} = [f(A) p^-(A)]_{i\bar{j}}$. 

**Lemma 10.27.** If $p \in \eta_A$, and $q \in \eta_A$, then $(p \ominus q) \in \eta_A$.

**Proof.** $(p^+ \ominus q^+)(A) = p^+(A) \ominus q^+(A)$, and $(p^- \ominus q^-)(A) = p^-(A) \ominus q^-(A)$ from Lemma 10.2.

Consider the $i^\text{th}$ element of $p^+(A) \ominus q^+(A)$. The $i^\text{th}$ element of $p^+(A) \ominus q^+(A)$ is one of the elements $[p^+(A)]_{i\bar{j}}$, or $[q^+(A)]_{i\bar{j}}$. Suppose, without loss of generality, that it is $[q^+(A)]_{i\bar{j}}$. Then $[q^+(A)]_{i\bar{j}} > [p^+(A)]_{i\bar{j}}$. Therefore, $[q^+(A)]_{i\bar{j}} > [p^+(A)]_{i\bar{j}}$, since $[p^+(A)]_{i\bar{j}} = [p^-(A)]_{i\bar{j}}$, and $[q^+(A)]_{i\bar{j}} = [q^-(A)]_{i\bar{j}}$. Therefore, $[p^+(A) \ominus q^-(A)]_{i\bar{j}} = [p^-(A)]_{i\bar{j}}$, and $[p^+(A) \ominus q^+(A)]_{i\bar{j}} = [p^+(A)]_{i\bar{j}}$.

**Lemma 10.28.** If $p \in \eta_A$, and $q \in \eta_A$, then $(p^+ \ominus q^-)(A) = (p^- \ominus q^+)(A)$.

**Proof.** Proof is similar to Lemma 10.27.

Consider the equation $(p^+ \ominus q^-)(A) = (p^- \ominus q^+)(A)$. Consider the $i^\text{th}$ element of each side. Without loss of generality, if $[p^+(A)]_{i\bar{j}} > [q^-(A)]_{i\bar{j}}$ then $[p^+(A)]_{i\bar{j}} = [p^-(A)]_{i\bar{j}} > [q^+(A)]_{i\bar{j}}$, and the result follows.

**Lemma 10.29.** If $p \in \eta_A$, and $q \in \eta_A$, then $(p \ominus q) \in \eta_A$. 

165
Proof. Let \( p=(p^+,p^-) \in \eta \) and \( q=(q^+,q^-) \in \eta \). So \( p^+(A) = p^-(A) \), and \( q^+(A) = q^-(A) \).

\[(p \otimes q)(A) = (p^+q^+ \uplus p^-q^- \uplus p^+q^- \uplus p^-q^+)(A)\]

We need to show that: \( p^+(A) q^+(A) \uplus p^-(A) q^-(A) = p^+(A) q^-(A) \uplus p^-(A) q^+(A) \) This follows from the identity, and use of Lemma 10.26 and Lemma 10.27: \( (p^+q^+ \uplus p^-q^- \uplus p^+q^- \uplus p^-q^+)(A) = p^+ \otimes (q^+,q^-) \uplus p^- \otimes (q^-,q^+) \).

Lemma 10.30. If \( p \in \eta_A \), and \( f \in \mathbb{P}^2 \), then \( (f \otimes p) \in \eta_A \).

Proof. Suppose \( p^+(A)=p^-(A) \), and \( f=(f^+,f^-) \in \mathbb{P}^2 \). Then \( f^+ \otimes p \in \eta_A \) and \( f^- \otimes (p^+,p^-) \in \eta_A \), by Lemma 10.26. Therefore, just as in 10.29, we have \( (f^+p^+ \uplus f^-p^-)(A) = (f^+p^- \uplus f^-p^+)(A) \). Therefore \( (f \otimes p) \in \eta_A \).

Theorem 10.31. \( \eta \) is an ideal of \( \mathbb{P}^2 \).

Proof.

1. Lemma 10.27 provides the proof that \( \eta_A \) is closed under \( \uplus \).

2. \( \otimes \): Lemma 10.29 provides the proof that \( \eta_A \) is closed under \( \otimes \).

3. Lemma 10.30 provides the proof that \( \otimes \) "captures" elements on \( \mathbb{P}^2 \).

\( \Box \)
11 Parallels

Many parallels exist between the Max-Times / Max-Plus algebras and the algebra of nonnegative matrices. Table 6 lists a few of the many parallels between these algebras.

Table 6: Parallels between Nonnegative and $\mathbb{M}^+$ matrices
12 Conclusions and Open Questions

As we have seen in Section 8 there is a theory which can be considered as a connection between the nonnegative numbers and the Max-Times algebra. The mset algebra has allowed us to catch a glimpse at one theory which connects these algebras. We have seen that a connection exists between the eigenvalue/eigenvector equations for the two algebras. The multisets are a tool which can be used for calculations in any semiring (and ring).

12.1 Open Questions

There are still many open questions related to this connection. In this section some of the open questions that have appeared are presented as a step toward continuing this research.

Example 12.1. An interesting equation developed, which was investigated. Although no full investigation was completed an elegant conjecture evolved. The proof will require more time to develop. The problem is to find a relationship between the msets for the following equation to hold: $\alpha \boxtimes \beta = \gamma \boxtimes \delta$.

The consistency condition requires that $|\alpha| \cdot |\beta| = |\gamma| \cdot |\delta|$.
The following conjecture has been developed.

**Conjecture 12.2.** If \( \alpha \boxtimes \beta = \gamma \boxtimes \delta \), then

\[
\begin{align*}
\alpha &= \alpha_1 \otimes \alpha_2 \cdots \otimes \alpha_n, \\
\beta &= \beta_1 \otimes \beta_2 \cdots \otimes \beta_\ell, \\
\gamma &= \gamma_1 \otimes \gamma_2 \cdots \otimes \gamma_s, \\
\delta &= \delta_1 \otimes \delta_2 \cdots \otimes \delta_t.
\end{align*}
\]

(355)

where the direct products of \( \gamma \) and \( \delta \) are composed of combinations of the parts of \( \alpha \) and \( \beta \).

Although some easier examples are certainly possible the following example is a fairly general example.

**Example 12.3.** Consider the true equation: \( \{1,2,4,8\} \boxtimes \{1,3,5,15\} = \{1,3,4,12\} \boxtimes \{1,2,5,10\} \)

In this example we see that each of the multisets can be decomposed into a direct product of multisets:

\[
\begin{align*}
\alpha &= \{1,2\} \boxtimes \{1,4\} \\
\beta &= \{1,3\} \boxtimes \{1,5\} \\
\gamma &= \{1,3\} \boxtimes \{1,4\} \\
\delta &= \{1,2\} \boxtimes \{1,5\}
\end{align*}
\]

A full investigation of this relation involves a deep understanding of permutations of the elements of rank one matrices.

**Conjecture 12.4.** If \( \alpha x \subseteq \beta x \), and \( |\beta| < |\alpha| \cdot |x| \), then \( \alpha \subseteq \beta \).

A full investigation of the analog to the matrix \( B^I \) over multisets is not complete. The question still remains as to how this matrix should be defined. One answer would be to define this as the infinite sum \( B^I = I \uplus B \uplus B^2 \uplus \cdots \) is okay, but this matrix is now over the power set \( 4^R \) of infinite multisets, which is no longer cancellative. We may need to look at the conditions for which the sum of the elements exists, such as the elements should be in \( \ell^1 \).

### 12.2 Questions to be answered about Polynomial Pairs

1. If \( f = (f^+, f^-) \in P^2 \), then \( \nu(A) \) is a root of \((f \otimes p)\), where \( p \) is characteristic equation of \( A \).

2. Is every root of a characteristic equation also a root of every equation in \( \eta_A \)?

170
3. Would it be possible to define \((p^+, p^-) \sim (q^+, q^-)\) if and only if 
\[ p^+(x) \oplus q^-(x) = p^-(x) \oplus q^+(x) \quad \forall x \in \mathbb{R}^+ \] 

4. Does the ideal \(\eta_A\) have a generator? If so, is the generator unique? If so, can we say that every element of \(\eta_A\) is divisible by the generator? This would lead to an association much like that of a PID.

5. Can we find a matrix with a non-monic minimal poly? I don’t think so, unless we go to a system which is not an integral domain, such as \(\mathbb{Z}/(12)\). For example see [25, p.164ff].

**Conjecture 12.5.** If \((p^+, p^-)\) is the characteristic equation of \(A\), and \(b\) is a root of \((p^+, p^-)\), then \(b\) is a root of \((f \odot p)\) for any \(f \in \mathbb{P}\)

**Conjecture 12.6.** \(\nu(A)\) is a root of every element of \(\eta_A\).

**Conjecture 12.7.** If \((p^+, p^-)\) is the characteristic equation of \(A\), and \(b\) is a root of \((p^+, p^-)\), then \(b\) is a root of every element of \(\eta_A\).

The next two examples concern the minimal polynomial of a matrix.

**Example 12.8.** Consider Example 9.4. If \(A=J_{3\times3}\), the characteristic equation is \(x^3 = x^2\), but it can be checked that \(x^2 = x\) is also an equation of smaller degree. Can we say that the polynomial equation of smaller degree divides the polynomial equation of larger degree? ■

In this example we first go from equations to polynomial pairs, and rephrase the question above as: Does \((x^2, x) | (x^3, x^2)\)?

This question can be answered in the affirmative, as it can be checked that 
\[(x, 0) \odot (x^2, x) = (x^3, x^2).\]

**Example 12.9.** If \(A=J_{3\times3}-I_{3\times3}\), then the characteristic equation is \(x^3 = x \oplus 1\), but it can be checked that \(x^2 = x \oplus 1\) is also an equation of smaller degree which is satisfied by the matrix. ■

In this example we first go from equations to polynomial pairs, and rephrase the question above as: Does \((x^2, x \oplus 1) | (x^3, x \oplus 1)\)?

This question can be answered in the affirmative, as it can be checked that 
\[(x \oplus 1, 0) \odot (x^2, x \oplus 1) = (x^3, x \oplus 1).\]
A Appendix

A.1 Basic Properties

Table 7 lists some basic facts about the following four algebra systems.

(a) Non-negative Real numbers
    (i) a ⊕ b = a + b
    (ii) a ⊗ b = a x b
    (iii) θ = 0 and e = 1
    (iv) \{ 0, + \} ⇔ \{ 0 , (>0) \}

(b) Boolean Algebra
    (i) a ⊕ b = \max(a,b)
    (ii) a ⊗ b = \min(a,b)
    (iii) θ = 0 and e = 1
    (iv) \{ 0, 1 \} ⇔ \{ 0 , (>0) \}

(c) Max-Plus Algebra
    (i) a ⊕ b = \max(a,b)
    (ii) a ⊗ b = a + b
    (iii) θ = −∞ and e = 0
    (iv) \{ −∞, (≠ −∞) \} ↦ \{ θ, (> θ) \}

(d) Max-Times Algebra
    (i) a ⊕ b = \max(a,b)
    (ii) a ⊗ b = a x b
    (iii) θ = 0 and e = 1
    (iv) \{ 0, + \} ⇔ \{ 0 , (>0) \}

A.2 Matlab programs for the Max-Plus Algebra System

This section contains some programs in Matlab to perform some of the elementary operations in the \((\text{max,+})\)-algebra.

function cout = oeye(n)
\% Returns the nxn identity matrix in the max-plus system.

cout=zeros(n,n);
for i=1:n
    for j=1:n
        if i==j
            cout(i,j)=0;
        else
            cout(i,j)=-inf;
        end
    end
end

function cout = otrace(a)
\% This function returns the trace of the matrix \(a\) in the
\% max-plus algebra system.
\% Requires: none.

if size(a,1)\neq size(a,2)
    disp('ERROR -- matrix must be square')
    return
end
    cout=-inf;
    for i=1:size(a,1)
        cout=max(cout,a(i,i));
    end

function cout = oplus(a,b)
\% calculates \(a+b\) in the max-plus algebra system
\% oplus(a,b)=max(a,b)
\% Requires: none.

cout=max(a,b);

function cout = otimes(a,b);
\% calculates the product of \(a\) and \(b\) in the max-times algebra.
\% Requires: none.

if max(size(a))==1
    cout=a+b;
elseif size(a,2) == size(b,1)
    disp('??? Error using ==> otimes')
    disp('Inner matrix dimensions must agree')
else
    kc=size(a,2); ar=size(a,1); bc=size(b,2);

A.5 UBASIC programs for Characteristic Polynomial

This appendix contains a program written in UBASIC to calculate the characteristic polynomial in the Max-Times Algebra system. UBASIC is a fast, and free, BASIC-interpreter capable of large number arithmetic.

```
10 ' This UBASIC program can be used to find the characteristic
20 ' equation for a matrix. It returns the list of
30 ' coefficients associated with the equation.
40 ' The program also returns the maximum eigenvalue for
42 ' the given matrix.
45 ' The program could be reworded to use
47 ' extended memory and increase the size of the matrix.
50 word 100 'Uses small numbers to get 5x5 matrices stored.
