NEGATIVE LATIN SQUARE DESIGNS

by

Dale M. Mesner

Purdue University and University of North Carolina

1. General properties of designs and association schemes. In a balanced or partially balanced incomplete block design, a collection of $b$ subsets, called blocks, is chosen from a set of $v$ objects, commonly called varieties or treatments, in such a way that every block contains the same number $k$ of objects, every object occurs in the same number $r$ of blocks, and a further regularity condition holds for the number of occurrences together within blocks of pairs of distinct objects. In a balanced incomplete block (BIB) design this number has the same value $\lambda$ for all pairs of distinct objects. In an $m$-class partially balanced incomplete block (PBIB) design [5, 16], any two distinct objects are related as first, second, ..., or $m$-th associates in accordance with rules to be stated in (1.1), and all pairs of objects which are $i$-th associates occur together in the same number $\lambda_i$ of blocks. The arrangement of pairs of distinct objects into associate classes is called an $m$-class association scheme and involves parameters $n_i, p_{jk}^i, i, j, k = 1, 2, ..., m$. We denote by $P_i$ the matrix whose element in the $j,k$ position is $p_{jk}^i$. Association schemes have been found useful in the combinatorial study of PBIB designs, as well as in the analysis of data from experiments in which these designs are applied. To each association scheme there corresponds a family of designs which share

---

1 Prepared with the partial support of the National Science Foundation, Grant GP-1660.
this association scheme and have common values of certain parameters, including
\( v, n_i, p^i_{jk} \), but which differ in the arrangement of objects into blocks and
in values of \( b, r, k, \) and \( \lambda_1 \).

An \( m \)-class association scheme with \( v \) objects is defined by the following
conditions \([6]\).

(i) Any two distinct objects are either first, second, ..., or \( m \)-th
associates.

(ii) Each object has \( n_i \) \( i \)-th associates, \( i = 1, \ldots, m \).

(iii) For any pair of the \( v \) objects which are \( i \)-th associates, the
number \( p^i_{jk} \) of objects which are \( j \)-th associates of the first
and \( k \)-th associates of the second is independent of the pair
of \( i \)-th associates with which we start.

The following are well-known identities which can be derived from this
definition.

\[
\sum_{i=1}^{m} n_i = v - 1,
\]

\[
p^i_{jk} = p^i_{kj},
\]

\[
\sum_{k=1}^{m} p^i_{jk} = n_i, \quad j \neq i,
\]

\[
= n_i - 1, \quad j = 1,
\]

\[
n_i p^i_{jk} = n_j p^j_{ik}.
\]

These relations among the parameters make it possible to simplify the
definition. A two-class association scheme with \( v \) objects may be defined
by the following conditions \([3]\).
(1.3) (i) Any two objects are either first or second associates.

(ii) Each object has $n_1$ first associates.

(iii) Given any two objects which are $i$-th associates, $i = 1, 2$, there are exactly $p_{11}^1$ other objects which are first associates of both.

Then, defining other parameters by

\begin{align*}
(1.4) \quad & n_1 + n_2 = v - 1, \\
& p_{12}^1 = p_{21}^1, \quad p_{12}^2 = p_{21}^2, \\
& p_{11}^1 + p_{12}^1 + 1 = p_{11}^2 + p_{12}^2 = n_1, \\
& p_{12}^1 + p_{22}^1 = p_{12}^2 + p_{22}^2 + 1 = n_2,
\end{align*}

each object has $n_2$ second associates and, given any two objects which are $i$-th associates, there are $p_{jk}^1$ other objects which are $j$-th associates of the first and $k$-th associates of the second. Also,

\begin{align*}
(1.5) \quad & n_1 p_{12}^1 = n_2 p_{11}^2, \quad n_1 p_{22}^1 = n_2 p_{12}^2.
\end{align*}

If $N$ is the $v \times b$ incidence matrix of objects and blocks in the design, then the $v \times v$ symmetric matrix $NN^T$ has only three distinct characteristic roots $\theta_0$, $\theta_1$, $\theta_2$, with multiplicities $\alpha_0$, $\alpha_1$, $\alpha_2$ respectively, where $\Sigma \alpha_i = v$. $\theta_0$ may be expressed

\begin{align*}
(1.6) \quad & \theta_0 = r + n_1 \lambda_1 + n_2 \lambda_2,
\end{align*}

and $\alpha_0 = 1$ if $NN^T$ is irreducible (equivalently if the design is connected). Then

\begin{align*}
(1.7) \quad & \alpha_1 + \alpha_2 = v - 1.
\end{align*}
If we define

\[(1.8) \quad \gamma = P_{12}^2 - P_{12}^1, \]
\[\Delta = \gamma^2 + 2P_{12}^1 + 2P_{12}^2 + 1,\]
\[\sigma = (\Delta^{\frac{1}{2}} - \gamma - 1)/2,\]
\[\tau = (\Delta^{\frac{1}{2}} + \gamma - 1)/2,\]

then it has been shown [13] that

\[(1.9) \quad \theta_1 = r + \lambda_1 \tau + \lambda_2 (\tau - 1),\]
\[\theta_2 = r + \lambda_1 (-\sigma - 1) + \lambda_2 \sigma,\]
\[(110) \quad \alpha_1 = [(\sigma + 1)n_2]^{\frac{1}{\Delta}},\]
\[\alpha_2 = [(\tau + 1)n_1 + \tau n_2]^{\frac{1}{\Delta}}.\]

The parameters \(\gamma, \Delta, \sigma, \tau, \alpha_1, \alpha_2\) depend only on the association scheme and not on blocks. Other known relations [17] that will be needed later are

\[(1.11) \quad vn_1n_2 = \Delta \alpha_1 \alpha_2,\]
\[(1.12) \quad P_{12}^1 = \sigma(\tau + 1),\]
\[P_{12}^2 = \tau(\sigma + 1).\]

If in a two-class association scheme we interchange the designation of first and second associates we obtain another association relation which satisfies (1.1). Two association schemes related in this way will be said to be complements of each other. If a scheme has parameters
\( n_1 = f, \quad p_1 = \begin{bmatrix} c & d \\ d & e \end{bmatrix}, \quad p_2 = \begin{bmatrix} f & g \\ g & h \end{bmatrix}, \)

its complement will have parameters

\( v, \quad n_1 = m, \quad p_1 = \begin{bmatrix} h & g \\ g & f \end{bmatrix}, \quad p_2 = \begin{bmatrix} e & d \\ d & c \end{bmatrix}. \)

There are \( m \)-class schemes for \( m > 2 \) which differ only by a permutation of associate classes, although the term "complement" is not appropriate in such cases.

Most known two-class PBIB designs have been classified by Bose and Shimamoto [6] into five types, distinguished primarily by the structure of their association schemes. The simplest type is group divisible, in which the \( v = mn \) objects are arranged into \( m \) disjoint groups of \( n \) objects, and objects are first associates if and only if they are in the same group.

For a group divisible scheme,

\[(1.13) \quad v = mn,\]

\[n_1 = n-1, \quad p_1 = \begin{bmatrix} n-2 & 0 \\ 0 & n(m-1) \end{bmatrix}, \quad p_2 = \begin{bmatrix} 0 & n-1 \\ n-1 & n(m-2) \end{bmatrix}.\]

Cyclic type schemes are defined in terms of certain combinatorial properties and have parameters which may be expressed as follows in terms of an integer \( t \).

\[(1.14) \quad v = 4t + 1,\]

\[p_1 = \begin{bmatrix} t-1 & t \\ t & t \end{bmatrix}, \quad p_2 = \begin{bmatrix} t & t \\ t & t-1 \end{bmatrix},\]

\[n_1 = n_2 = \alpha_1 = \alpha_2 = 2t.\]
Association schemes with parameters (1.12), whatever their combinatorial structure, will be called pseudo-cyclic. In the next section we take up Latin square association schemes, another type in the Bose-Shimamoto classification, then introduce the new family of designs, negative Latin square, which are the principal topic of this paper.

2. **Negative Latin square designs.** An association scheme of Latin square type with \( v = n^2 \) objects and \( g \) constraints, which we denote as an \( L_g(n) \) scheme, is defined by an \( n \times n \) square array of the objects and a set of \( g \)-2 pairwise orthogonal Latin squares of order \( n \). Two objects are first associates if and only if they occur in the same row or column of the array or in positions occupied by the same letter in any of the Latin squares. If to the set of Latin squares we adjoin two more \( n \times n \) arrays of \( n \) letters, one in which the \( i \)-th letter occupies all positions in the \( i \)-th row and another in which the \( i \)-th letter occupies all positions in the \( i \)-th column, we have \( g \) pairwise orthogonal squares (not all Latin) and may define first associates somewhat more symmetrically as objects which occur in positions occupied by the same letter in any of the squares. Finite nets [7, 9] and orthogonal arrays [11] may be used as the basis for equivalent definitions. \( L_g(n) \) parameters are given by

\[
(2.1) \quad v = n^2,
\]

\[
n_1 = g(n-1), \quad p_1 = \begin{bmatrix} (g-1)(g-2)+n-2 & (n-g+1)(g-1) \\ (n-g+1)(g-1) & (n-g+1)(n-g) \end{bmatrix},
\]

\[
n_2 = (n-g+1)(n-1), \quad p_2 = \begin{bmatrix} g(g-1) & g(n-g) \\ g(n-g) & g(n-g)(n-g-1)+n-2 \end{bmatrix}.
\]
These lead to further parameters

\begin{equation}
\sigma = g-1, \quad \tau = n-g, \quad \Delta = n^2 ,
\end{equation}

\[\alpha_1 = g(n-1), \quad \alpha_2 = (n-g+1)(n-1) .\]

Association schemes with parameters (2.1), whatever their combinatorial structure, will be called pseudo-Latin square.

Since there can be at most \(n-1\) pairwise orthogonal Latin squares of order \(n\), \(g\) cannot exceed \(n+1\); moreover, if \(g = n+1\), all pairs of objects are first associates and the design reduces to a BIB design. The result is the same with \(g = 0\).

A Latin square association scheme with \(g = 1\) constraint is a special case of a group divisible scheme, while it is easy to show that its complement has this structure in the case \(g = n\). We may therefore assume

\begin{equation}
2 \leq g \leq n-1 .
\end{equation}

We observe that the complement of a Latin square association scheme with \(g\) constraints is a pseudo-Latin square scheme with \(n+1-g\) constraints. This was illustrated in the preceding paragraph and becomes obvious if we use the brief notation \(f = n+1-g\) and note pairs of symmetric expressions such as

\[n_1 = g(n-1), \quad n_2 = f(n-1),\]

and

\[p_{22}^1 = f(f-1), \quad p_{11}^2 = g(g-1) .\]

As a result, any pseudo-Latin square association scheme may be reduced by choice of notation to a pseudo-Latin square scheme with

\begin{equation}
2 \leq g \leq (n+1)/2 .
\end{equation}
These are simply the schemes of this family for which \( n_1 \leq n_2 \). An example will show that not all pseudo-Latin square schemes have Latin square structure. An \( L_3(6) \) scheme can be constructed from any 6x6 Latin square. Its complement then has \( L_4(6) \) parameters but cannot have Latin square structure since no set of 4-2 = 2 orthogonal 6x6 Latin squares exists. On the other hand, it is known [21, 9, 16] for a wide range of values of \( n \) and \( g \) that an association scheme with parameters (2.1) necessarily corresponds to a set of \( g-2 \) pairwise orthogonal Latin squares of order \( n \).

While minor infringements of inequality (2.3) lead only to trivial special cases, we now obtain something interesting by committing a major violation. Negative values of \( n \) and \( g \) lead in many cases to parameters (2.1) which are non-negative integers. These parameters satisfy conditions (1.4) and (1.5), which reduce to algebraic identities in \( n \) and \( g \), but differ from the parameters of any of the types of association schemes in the Bose-Shimamoto classification. This suggests the existence of a new series of 2-class PBIB designs, based on association schemes with such parameters. The name negative Latin square will be used for designs and association schemes in the new series. The simplest case is \( n = -4 \), \( g = -1 \), giving the following, which could be termed \( L_{-1}(-4) \) parameters.

\[
\begin{align*}
v &= 16, \\
n_1 &= 5, & P_1 &= \begin{bmatrix} 0 & 4 \\ 4 & 6 \end{bmatrix}, & P_2 &= \begin{bmatrix} 2 & 3 \\ 3 & 6 \end{bmatrix}, \\
n_2 &= 10,
\end{align*}
\]
Designs are known with these parameters, showing that the negative Latin square family of designs is not vacuous.

Instead of using (2.1) with negative arguments for negative Latin square parameters it is convenient to have expressions in terms of positive arguments, which we shall still denote, however, by the same letters n and g. Then using the negative integers -n and -g in (2.1) we arrive at

\[(2.5) \quad v = n^2, \quad p_1 = \begin{bmatrix} (g+1)(g+2) - n - 2 & (n-g-1)(g+1) \\ (n-g-1)(g+1) & (n-g-1)(n-g) \end{bmatrix}, \]
\[n_1 = g(n+1), \quad n_2 = (n-g-1)(n+1), \quad p_2 = \begin{bmatrix} g(n+1) & g(n-g) \\ g(n-g) & (n-g)(n-g+1) - n^2 \end{bmatrix}.\]

In terms of the positive integers n and g, we denote these as NL\(g\)(n) parameters.

Using (2.5) in (1.8) and (1.10),

\[(2.6) \quad \sigma = n-g-1, \quad \tau = g, \quad \Delta = n^2, \]
\[\alpha_1 = (n-g-1)(n+1), \quad \alpha_2 = g(n+1).\]

Alternatively, values of \(\sigma, \tau, \alpha_1\) could be obtained by using the negative integers -n and -g in (2.2). This amounts to using the negative square root of \(\Delta\) in (1.8) and leads to negative values of \(\sigma\) and \(\tau\), finally giving values of \(\theta_1\) and \(\alpha_1\) which differ from those of (1.9) and (2.6) by an interchange of indices 1 and 2. In adopting expressions (2.6) we are following the customary [13] notation for \(\sigma_1\) and \(\alpha_1\).

The abbreviations \(L_g(n)\) and \(NL_g(n)\) will sometimes be shortened to \(L_g\) and \(NL_g\) when it is not necessary to specify the value of n.

Like the pseudo-Latin square family, which is also defined in terms of the form of its parameters, the negative Latin square family of association
schemes contains the complement of each of its members; specifically, the complement of an NL_g(n) scheme is an NL_{n-g-1}(n) scheme. As a result, any negative Latin square scheme may be reduced by choice of notation to one for which

\[ g \leq \frac{1}{2}(n-1), \]

or equivalently

\[ n_1 \leq n_2. \]

The requirement that \( p_{11} \) is non-negative places a lower bound on \( g \).

If \( n \) is odd, we note that \( L_{1,\frac{1}{2}(n+1)}(n) \) parameters are identical with \( NL_{\frac{1}{2}(n-1)}(n) \) parameters and that both agree with pseudo-cyclic parameters (1.14) with argument \( t = (n^2-1)/4 \). These are the only \( L_g \) or \( NL_g \) schemes for which \( n_1 = n_2 \) and the only pseudo-cyclic schemes for which \( v \) is a square.

No other schemes are common to any two of these three families.

All \( NL_g(n) \) parameters satisfying \( n_1 \leq n_2 \) are listed in the following table for the range \( n \leq 10 \). The six schemes which were previously known and the four which are constructed for the first time in the present paper are identified in the "Remarks" column, together with references to publications, to known schemes in the Latin square family, and to sections of this paper in which constructions are presented. Parameters of designs with \( NL_g(n) \) association schemes will be tabulated in Section 9.

3. A characterizing property. We observe that for association schemes of pseudo-cyclic, pseudo-Latin square and negative Latin square types, the multiplicities \( \alpha_1, \alpha_2 \) of the characteristic roots of \( NN^T \) are equal in some order to the numbers \( n_1, n_2 \) of objects in the two associate classes. This proves sufficiency in the following theorem. The necessity statement shows that this property characterizes these three types of association schemes.

Theorem 3.1. In order for the parameters \( \alpha_1, \alpha_2 \) in a two-class association scheme to be equal in some order to the parameters \( n_1, n_2 \), it is necessary and sufficient that the scheme be of pseudo-cyclic, pseudo-Latin square or negative Latin square type.

Before completing the proof of this theorem, we state a simple lemma.

Lemma 3.1. The parameters \( \alpha_1, \alpha_2 \) in a two-class association scheme are equal in some order to the parameters \( n_1, n_2 \) if and only if \( \nu = \Delta \).

Proof of lemma. From (1.4) and (1.7),

\[
n_1 + n_2 = \alpha_1 + \alpha_2.
\]

The lemma follows from this and (1.11).

Proof of theorem (necessity). If the scheme is of pseudo-cyclic type we are finished. If not, then by Theorems 5.3 and 5.5 of [13], \( \Delta \) is the square of an integer \( n \), and using the lemma,

\[
n^2 = \Delta = \nu.
\]

Then

\begin{equation}
(3.1) \quad n_2 = n^2 - 1 - n_1.
\end{equation}
Using (1.8),

\[ \sigma + \tau + 1 = \Delta^2 = n, \]  

(3.2) \hspace{1cm} partially identifying \( \sigma \) and \( \tau \).

**Case I.** Suppose \( n_1 = \alpha_1 \). Then from (1.10) and (3.1),

\[ n_1 = [\sigma n_1 + (\sigma+1)(n^2-1-n_1)]/n, \]

reducing to

\[ n_1 = (\sigma+1)(n-1). \]

This identifies \( \sigma \) and \( \tau \) completely. If we set \( \sigma+1 = g \) we have

\[ n_1 = g(n-1), \]

\[ n_2 = (n-g+1)(n-1), \]

and from (1.12),

\[ p_{12}^1 = (g-1)(n-g+1), \]

\[ p_{12}^2 = g(n-g). \]

The parameters \( v, n_1, p_{12}^1 \) are of the form of (2.1), and it follows from (1.4) that the same is true of the remaining \( p_{jk}^1 \). Therefore the scheme is of pseudo-Latin square type.

**Case II.** Suppose \( n_1 = \alpha_2 \). Then using (1.10) and (3.1) as in Case I we find

\[ n_1 = \tau(n+1) \]

and setting \( \tau = g \) we again use (1.12), this time arriving at parameters of
the form of (2.5). Therefore, the scheme is of negative Latin square type and the proof is complete.

It is clear from Lemma 3.1 that the condition on $n_1$ and $\alpha_1$ in Theorem 3.1 could be replaced by the condition $v = \Delta$. The fact that $v$ is a square is a distinctive property of the Latin square and negative Latin square schemes but is not peculiar to them, as shown, for example, by numerous group divisible schemes and by the triangular scheme with $v = 36$. However, inspection of a list of arithmetically possible parameters for two-class association schemes leads to the interesting conjecture that when $v$ is a square, a high proportion of these parameters fall in the group divisible, $L_g$ and $NL_g$ series. As an illustration, in the range $v \leq 100$, $v$ a square, $n_1 \leq n_2$: there are at most 65 sets of two-class parameters, of which 59 are in these three series.

4. Some Preliminary Theorems. Several results, most of them from other sources, which will be needed in Sections 5 and 7 for the construction of association schemes, are collected in this section for convenient reference.

In an association scheme with classes 1, ..., $m$, we may introduce a zero-th associate class by letting each object be the zero-th associate of itself and of no other object. We define additional parameters

$$n_0 = 1,$$

$$p_{ij}^0 = n_1 \text{ if } i = j,$$

$$= 0 \text{ otherwise,}$$

$$p_{0i}^1 = p_{ki}^1 = 1 \text{ if } i = k,$$

$$= 0 \text{ otherwise.}$$
This convention increases the conciseness and symmetry of many statements about association schemes and their parameters. We shall retain the term "m-class" for a scheme with classes 0, 1, ..., m.

The method of differences was introduced for construction of incomplete block designs in the module theorem of Bose and Nair [5] and later stated in somewhat greater generality by Sprott [23]. The following is the portion of the theorem which applies to association schemes, using the terminology of the zeroth associate class.

Theorem 4.1. Module theorem. Let the elements of an additive Abelian group G of finite order v be partitioned into disjoint sets \( \mathcal{Q}_0 = \{0\}, \mathcal{Q}_1, \ldots, \mathcal{Q}_m \). Let \( \mathcal{Q}_i \) contain \( n_i \) elements, denoted by

\[
\mathcal{Q}_i = \{a_{i,1}, a_{i,2}, \ldots, a_{i,n_i}\}.
\]

We set up an association relation among the elements of G by taking \( y \) as an \( i \)-th associate of \( x \) if and only if the difference \( y - x \) is in \( \mathcal{Q}_i \). Then each element has \( n_i \) \( i \)-th associates, and the relation is an m-class association scheme with parameters \( v, n_i, p_{jk}^i \) if and only if

(i) each group element is in the same \( \mathcal{Q}_i \) as its inverse;

(ii) for any \( i, j, k \) in the range 0, 1, ..., m, and for any fixed element \( x \in \mathcal{Q}_i \), there are exactly \( p_{jk}^i \) ordered pairs \( u, w \), where

\[
1 \leq u \leq n_j, \quad 1 \leq w \leq n_k, \quad \text{such that}
\]

\[
(a_{i,u} - a_{i,w}) = x.
\]

Our application of the module theorem will be to the additive group of a finite field, using the multiplicative group in the construction of the sets \( \mathcal{Q}_i \). Our procedure is similar to that of Sprott, but a self-con-
tained account will be given here.

Theorem 4.2. In a finite field of order \( v \) with additive group \( G \) and multiplicative group \( G' \), let \( m \) be a divisor of the order \( v-1 \) of \( G' \) such that \( N = (v-1)/m \) is even if \( v \) is odd, and let \( \xi \) be a generator of \( G' \). Let \( G_0 = \{ 0 \} \), let \( G_1 \) be the multiplicative subgroup of order \( N \) generated by \( \xi^m \), and let \( G_i, i = 2, \ldots, m, \) be the coset of \( G_1 \) which contains \( \xi^{i-1} \). Define an association relation \( \gamma(v, m) \) in which two elements \( x, y \) of \( G \) are \( i \)-th associates if and only if \( y-x \in G_i, \ i = 0, 1, \ldots, m. \) Then for \( i, j, k \) in the range \( 1, \ldots, m \) and interpreted modulo \( m \) where necessary,

\[
\gamma(v, m) \text{ is an } m \text{-class partially balanced association scheme with parameters } v, n_1 = N, p_{jk}^1.
\]

\[
p_{jk}^i = p_{j+1}^i, k+1 = p_{j-i+1}^i, k-1+1.
\]

\[
p_{jk}^i \text{ is equal to the number of elements of } G_{j-i+1} \text{ which occur in the set obtained by adding the unit element } 1 \text{ to each element of } G_{k-i+1}.
\]

Proof. To prove (4.2) we shall verify that the sets \( G_i \) satisfy conditions (i) and (ii) of Theorem 4.1. The first of these conditions is automatic if \( v \) is even, since in this case every nonzero element is of order 2 and is its own additive inverse. If \( v \) is odd, the unit element 1 is given by

\[
l = \xi^{mN}
\]

and its additive inverse is given by

\[-1 = (\xi^m)^{N/2},\]
where \( N/2 \) is an integer by hypothesis. Therefore \(-1\) is an element of

the subgroup \( G_1 \) generated by \( \xi^m \). It follows that for every element \( y \) of any

\( G_1 \), \(-y = y(\xi^m)^{N/2}\) is also in \( G_1 \), verifying condition (i) of Theorem 4.1.

An element \( x = a_{i,t} \in G_1 \) may be expressed

\[
a_{i,t} = \xi^{mt} + i - 1,
\]

and (4.1) may be written

\[
(4.5) \quad \xi^{mu} + j - 1 - \xi^{mw} + k - 1 = \xi^{mt} + i - 1.
\]

This equation is equivalent to

\[
(4.6) \quad \xi^{m(u-t)} + j - 1 - \xi^{m(w-t)} + k - 1 = \xi^{i-1}.
\]

As \( u \) and \( w \) range independently over the residue classes 1, 2, ..., \( N \) modulo

\( N \), the same is true of \( u-t \) and \( w-t \). Then each of \( \xi^{m(u-t)} \) and \( \xi^{m(w-t)} \) ranges

over \( G_1 \), and the two terms in the left hand side of (4.6) range independently

over \( G_j \) and \( G_k \). The number of solutions \( u,w \) of (4.1) and of (4.5) is thus

equal to the number of solutions of

\[
(4.7) \quad a_{j,u} - a_{k,w} = \xi^{i-1}.
\]

But this is independent of \( t \) and hence of the particular element \( x \) chosen

from \( G_1 \). Denoting the number of solutions by \( p_{jk}^1 \), we have verified condition

(ii) of Theorem 4.1, completing the proof of (4.2).

Multiplying (4.5) by \( \xi^d \) gives the equivalent equation

\[
(4.8) \quad \xi^{mu} + j + d - 1 - \xi^{mw} + k + d - 1 = \xi^{mt} + i + d - 1,
\]
which has the same number \( p_{jk}^i \) of solutions for fixed \( i, j, k, t \). But this number of solutions may also be interpreted as \( p_{j+d, k+d}^{i+d} \) where indices are reduced modulo \( m \) to fall in the range \( 1, 2, \ldots, m \). \( s^d \) and \( s^{d-m} \) are in the same coset of \( G_1 \), and reducing modulo \( m \) merely means that the cosets are still designated by the representatives named in the theorem. With this interpretation of indices, we have

\[
p_{jk}^i = p_{j+d, k+d}^{i+d},
\]

and two special cases give (4.3).

From (4.7), \( p_{jk}^1 \) is the number of solutions \( u, w \) of

(4.9) \[ a_j u = a_k w + 1, \]

that is, the number of elements of \( G_j \) in the set obtained by adding the unit element 1 to each element of \( G_k \). Together with (4.3) this gives (4.4) and completes the proof of Theorem 4.2.

Determining the \( m^3 \) parameters \( p_{jk}^i \) of an \( m \)-class association scheme is considerably simplified for the \( \mathcal{J}(v, m) \) schemes by (4.3), which says that matrices \( P_2, \ldots, P_m \) may be obtained from \( P_1 \) by cyclic permutation of rows and columns. The standard relations \( p_{jk}^i = p_{kj}^i \) and \( n_i p_{jk}^i = n_j p_{jk}^i \), the latter of which may be simplified because \( n_i = n_j \), reduce the \( m^2 \) parameters \( p_{jk}^1 \) to a subset of approximately \( m^2/6 \) of them. The analogous number of independent parameters in the absence of (4.3) is \( m^3/6 \). Enumerating solutions of (4.9) to find the independent \( p_{jk}^1 \) values is still a non-trivial problem. It can be reduced to finding the number of ordered pairs \( u, w \), where \( 0 \leq u < m \), \( 0 \leq w < m \), such that the equation
(4.10) \[ \xi^{j+mu} + \xi^{k+mw} + 1 = 0 \]

holds in GF(v). This problem in finite fields has been extensively studied, especially in the case of prime \( v \), but not solved completely. A survey is given in [8].

For given \( v \), \( m \), the association scheme \( \mathcal{J}(v,m) \) is determined uniquely up to a certain permutation of associate classes 2, 3, ..., \( m \). Since \( G' \) is a cyclic group, the subgroup \( G_1 \) of a given order \( N \) is unique, and with it the first associate class. The partition of \( G' \) into cosets is also unique. However, there are \( \varphi(v-1) \) choices of the generator \( \xi \), where \( \varphi \) is the Euler totient function, and different choices may result in different assignments of the indices 2, ..., \( m \) to the cosets. The indexing of elements within cosets will also be affected, but this is irrelevant for the association schemes. If \( s \) is a positive integer less than and prime to \( m \), and if instead of the generator \( \xi \) we use a generator \( \eta \) such that

\[ \xi = \eta^t, \]

\[ t = s \mod m, \]

then the coset representative \( \xi^{i-1} \) will be expressed

\[ \xi^{i-1} = \eta^{s(i-1)} \]

and the \( i \)-th associate class in our original formulation will receive a new index congruent modulo \( m \) to \( 1 + s(i-1) \). The number of different permutations of associate classes that can arise for a given \( v \) and \( m \) will thus be \( \varphi(m) \), the number of possible values of \( s \).
The association matrices $A_0$, $A_1$, ..., $A_m$ of an $m$-class association scheme are matrices of order $v$ defined by

\[(4.11)\quad A_0 = I, \quad A_1 = (a_{\mu \nu}^{(1)}),\]

where

\[a_{\mu \nu}^{(1)} = 1 \text{ if objects } \mu \text{ and } \nu \text{ are } i\text{-th associates},\]

\[= 0 \text{ otherwise.}\]

Clearly $A_i$ is a symmetric matrix with all row and column sums equal to $n_i$.

We may prove [24, 4]

**Theorem 4.3.** Matrices $A_0 = I$, $A_1$, ..., $A_m$ are association matrices of an $m$-class partially balanced association scheme with parameters $v$, $n_i = n^0_i$, $p_{jk}^i$ if and only if

\[(4.12)\quad \text{each } A_i \text{ is a symmetric } v \times v \text{ matrix of 0's and 1's},\]

\[(4.13)\quad \sum_{i=0}^{m} A_i = J, \text{ the } v \times v \text{ matrix of 1's},\]

\[(4.14)\quad A_j A_k = \sum_{i=0}^{m} p_{jk}^i A_i, \quad j, k = 0, 1, ..., m.\]

This theorem can be simplified as follows in the case $m = 2$.

**Theorem 4.4.** $A_1$ is the first association matrix of a 2-class partially balanced association scheme with parameters $v$, $n_i$, $p_{jk}^i$ if and only if, defining $A_2 = J - I - A_1$,

\[(4.15)\quad A_1 \text{ and } A_2 \text{ are symmetric } v \times v \text{ matrices of 0's and 1's},\]

\[(4.16)\quad A_1^2 = n_l I + p_{ll}^1 A_1 + p_{ll}^2 A_2.\]

Useful information can be obtained from certain submatrices of association matrices. We partition matrices $A_1$ and $A_2$ for a 2-class scheme.
into submatrices whose sets of rows and columns correspond to an initial object $\alpha$, the set of $n_1$ first associates of $\alpha$, and the set of $n_2$ second associates of $\alpha$. For convenience, we may choose notation so that $\alpha$ is in leading position with its first associates in the next $n_1$ positions. The following illustrates the partition and defines notation for the submatrices.

\begin{equation}
(4.17) \quad A_1 = \begin{bmatrix}
0 & 1 & \ldots & 1 & 0 & \ldots & 0 \\
1 & \ddots & & & \ddots & & \\
\vdots & \ddots & \ddots & & & \ddots & \\
0 & \ddots & \ddots & \ddots & & & \\
1 & & & & & & \\
0 & & & & & & \\
0 & & & & & & \\
\end{bmatrix} \quad , \quad A_2 = \begin{bmatrix}
0 & 0 & \ldots & 0 & 1 & \ldots & 1 \\
0 & \ddots & & & \ddots & & \\
\vdots & \ddots & \ddots & & & \ddots & \\
\vdots & \ddots & \ddots & \ddots & & & \\
0 & \ddots & \ddots & \ddots & & & \\
1 & & & & & & \\
C_2 & D_2 & & & & & \\
\end{bmatrix}
\end{equation}

$B_1$ and $B_2$ are symmetric $n_1 \times n_1$ matrices; $D_1$ and $D_2$ are symmetric $n_2 \times n_2$ matrices.

Lemma 4.5. Submatrices $B_1$, $C_1$, $C_1^T$, $D_1$ have uniform row totals $p_1^1$, $p_1^2$, $p_1^3$, $p_1^4$ respectively.

Proof. The inner product of rows $\theta$ and $\varphi$ of $A_1$ is equal to the number of first associates common to objects $\theta$ and $\varphi$. The results for $B_1$ and $C_1^T$ are obtained by setting $\theta = 1$ while $\varphi$ ranges over the remaining rows. The results for $C_1$ and $D_1$ follow by subtraction from the uniform row totals $n_1$ of $A_1$.

Theorem 4.6. A partitioned matrix $A_1$ of the form (4.17) is the first association matrix of a two-class partially balanced association scheme with parameters $v$, $n_1$, $p_{jk}^1$ if and only if, defining $A_2 = J - I - A_1$, and defining submatrices of $A_2$ by (4.17),

\begin{equation}
(4.18) \quad A_1 \text{ and } A_2 \text{ are matrices of 0's and 1's,}
\end{equation}
\[(4.19)\] \(B_1\) and \(D_1\) are symmetric matrices of order \(n_1\) and \(n_2\) respectively,

\[(4.20)\] \(B_1\) has row sums \(p^{1}_{11}\) and \(C_1^T\) has row sums \(p^{2}_{11}\),

\[(4.21)\] \(J + B_1^2 + C_1 C_1^T = n_1 I + p^{1}_{11} B_1 + p^{2}_{11} B_2\),

\[(4.22)\] \(B_1 C_1 + C_1 D_1 = p^{1}_{11} C_1 + p^{2}_{11} C_2\),

\[(4.23)\] \(C_1^T C_1 + D_1^2 = n_1 I + p^{1}_{11} D_1 + p^{2}_{11} D_2\).

Proof. If \(A_1\) is any partitioned matrix of the form given in \((4.17)\), the square of \(A_1\) is given in part by

\[(4.24)\]

\[
A_1^2 = \begin{bmatrix}
J + B_1^2 + C_1 C_1^T & B_1 C_1 + C_1 D_1 \\
C_1^T B_1 + D_1 C_1^T & C_1^T C_1 + D_1^2
\end{bmatrix}
\]

Now suppose \(A_1\) is the first association matrix of the specified two-class scheme. Then \((4.18)\) to \((4.20)\) hold, \((4.16)\) holds and implies

\[(4.25)\]

\[
A_1^2 = \begin{bmatrix}
\begin{array}{cccc}
n_1 & p^{1}_{11} & \cdots & p^{1}_{11} \\
p^{1}_{11} & \ddots & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots \\
p^{1}_{11} & \ddots & \ddots & \ddots \\
p^{1}_{11} & \ddots & \ddots & \ddots \\
p^{2}_{11} & \ddots & \ddots & \ddots \\
p^{2}_{11} & \ddots & \ddots & \ddots \\
p^{2}_{11} & \ddots & \ddots & \ddots \\
p^{2}_{11} & \ddots & \ddots & \ddots \\
\end{array}
\end{bmatrix}
\]

and comparison of \((4.24)\) and \((4.25)\) gives \((4.21)\) to \((4.23)\).
Conversely, suppose $A_1$ satisfies (4.18) to (4.23). (4.18) and (4.19) imply (4.15). (4.24) holds, and with the aid of (4.17) to (4.20) the first row and column of $A^2_1$ may be shown to be as in (4.25), while (4.21) to (4.23) give the rest of (4.25). But (4.25) implies (4.16), and by Theorem 4.4, $A_1$ is the first association matrix of a two-class scheme with the specified parameters.

While our primary concern in this paper is with association schemes, some balanced and partially balanced designs will be discussed in Sections 7 and 8. The next theorem and corollary are well-known characterizations of these designs in terms of the incidence matrix $N$ of objects and blocks.

Theorem 4.7. $N$ is the incidence matrix of objects and blocks in a PBD design with parameters $v, b, r, k, \lambda_i, \mu$, and $p_{jk}$ if and only if

(i) $N$ is a $v \times b$ matrix of 0's and 1's,
(ii) every column of $N$ contains exactly $k$ 1's,
(iii) $NN^T = rI + \lambda_1 A_1 + \ldots + \lambda_m A_m$, where
(iv) $A_1, \ldots, A_m$ satisfy the conditions of Theorem 4.3 or Theorem 4.4.

Corollary 4.7.1. $N$ is the incidence matrix of objects and blocks in a BIB design with parameters $v, b, r, k, \lambda_i$, if and only if

(i) $N$ is a $v \times b$ matrix of 0's and 1's
(ii) Every column of $N$ contains exactly $k$ 1's,
(iii) $NN^T = rI + \lambda(J-I)$.

A matrix of the form $rI + \lambda_1 A_1 + \ldots + \lambda_m A_m$, whether or not it arises as a product $NN^T$, has characteristic roots whose values and multiplicities are of some interest and have been discussed, for example, in [4]. In the case $m = 2$ they are given by expressions (4.6) to (1.8) in this paper.
It is sometimes possible to construct an m-class association scheme \( \mathcal{G} \) by the device of combining associate classes in an \( \hat{m} \)-class scheme \( \hat{\mathcal{G}} \) with the same \( v, \hat{m} > m \). In terms of association matrices, this means that the matrices \( \hat{A}_1, \ldots, \hat{A}_m \) of scheme \( \hat{\mathcal{G}} \) are arranged into \( m \) disjoint non-empty sets, and the \( i \)-th association matrix of \( \mathcal{G} \) is taken as the sum of all matrices in the \( i \)-th set. The resulting association relation does not in general meet the conditions of partial balance; necessary and sufficient conditions that it will do so are derived in Theorem 5.1 of [4] and are stated in Theorem 4.8 below for the case \( m = 2 \). We continue to use the notion of the zero-th associate class.

Theorem 4.8. Given a partially balanced association scheme \( \hat{\mathcal{G}} \) with more than two classes and with parameters \( v, \hat{n}_\alpha, \hat{P}_{\beta \gamma}^{\alpha} \), let the indices of the associate classes be partitioned into disjoint sets \( S_0 = \{0\}, S_1, S_2 \). Define a two-class association relation \( \mathcal{G} \) in which two objects are taken as \( i \)-th associates if and only if their associate class in \( \hat{\mathcal{G}} \) has its index in \( S_1 \). Then \( \mathcal{G} \) satisfies the conditions of partial balance if and only if, for \( i = 0, 1, 2 \) and for some integers \( p_{11} \),

\[
(4.26) \quad \sum_{\beta, \gamma \in S_1} \hat{P}_{\beta \gamma}^{\alpha} = p_{11}^i, \text{ uniformly for } \alpha \in S_1.
\]

If (4.26) is satisfied, \( \mathcal{G} \) has parameters \( v, p_{11}^i \), where \( n_1 = p_{11}^0 \) and the other parameters \( n_2, p_{jk}^i \) are defined by the standard identities (1.3).

We note that for \( i = 0 \), (4.26) reduces to the statement \( \sum_{\alpha \in S_1} \hat{n}_\alpha = n_1 \), which is equivalent to \( \sum_{\alpha \in S_2} \hat{n}_\alpha = n_2 \). For \( i = 1, 2 \), the left hand side of (4.26) represents \( p_{11}^i \) as the sum of the elements of a submatrix of \( \hat{P}_\alpha \).

Somewhat more generally, if (4.26) is satisfied, then for \( i, j, k = 1, 2, \ldots \),
and for any $\alpha \in S_i$, $\hat{P}_{jk}^i$ is the sum of the elements of the submatrix of $\hat{P}_\alpha$ which has $S_j$ as its set of row indices and $S_k$ as its set of column indices.

Example. As the objects in an association relation $\hat{C}$ take the 16 ordered quadruples

\[
\begin{array}{cccccc}
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 1 \\
0 & 1 & 1 & 1 & 0 & 1 \\
\end{array}
\begin{array}{cccccc}
0 & 0 & 1 & 0 & 0 & 1 \\
0 & 1 & 0 & 1 & 1 & 1 \\
1 & 0 & 0 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

and take two objects as $i$-th associates if they differ in exactly $i$ positions. By interpreting the quadruples as rectangular coordinates we may interpret the objects as the 16 vertices of the 4-dimensional unit cube, two vertices being $i$-th associates if their distance is $\sqrt{i}$. $\hat{C}$ is found to be a 4-class association scheme with parameters

$v = 16, \\
\hat{n}_1 = 4, \\
\hat{n}_2 = 6, \\
\hat{n}_3 = 4, \\
\hat{n}_4 = 1, \\
\hat{p}_1 = \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \hat{p}_2 = \begin{bmatrix} 2 & 0 & 2 \\ 0 & 4 & 0 \\ 2 & 0 & 2 \end{bmatrix}, \hat{p}_3 = \begin{bmatrix} 0 & 3 & 0 \\ 3 & 0 & 3 \\ 0 & 3 & 0 \end{bmatrix}, \hat{p}_4 = \begin{bmatrix} 0 & 0 & 4 \\ 0 & 4 & 0 \\ 4 & 0 & 0 \end{bmatrix}.$

The matrices $\hat{P}_\alpha$ are repeated below, with $\hat{P}_0$ included and with zero-th row and column adjoined to each to display the $\hat{P}_\beta^\gamma$ with zero indices. We now combine associate classes, taking $S_0 = \{0\}, S_1 = \{3, 4\}, S_2 = \{1, 2\}$. The matrices below are partitioned into the submatrices described in the preceding paragraph.
\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 4 & 0 & 0 \\
0 & 0 & 6 & 0 \\
0 & 0 & 0 & 4 \\
0 & 0 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 3 & 0 \\
0 & 3 & 0 & 3 \\
0 & 0 & 3 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
0 & 0 & 1 & 0 \\
0 & 2 & 0 & 2 \\
1 & 0 & 4 & 0 \\
0 & 2 & 0 & 2 \\
0 & 0 & 1 & 0
\end{bmatrix},
\begin{bmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 4 \\
0 & 0 & 6 & 0 \\
0 & 4 & 0 & 0 \\
1 & 0 & 0 & 0
\end{bmatrix}\]

\[
\begin{bmatrix}
0 & 0 & 1 & 0 \\
0 & 3 & 0 & 1 \\
0 & 3 & 0 & 3 \\
1 & 0 & 3 & 0 \\
0 & 1 & 0 & 0
\end{bmatrix},
\begin{bmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 4 & 0 \\
0 & 0 & 0 & 3 \\
0 & 0 & 0 & 0
\end{bmatrix}\]

The submatrices over which the sum in \((4.26)\) is taken are, respectively,

\[
\begin{bmatrix}
4 & 0 \\
0 & 1
\end{bmatrix},
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix},
\begin{bmatrix}
2 & 0 \\
0 & 0
\end{bmatrix},
\begin{bmatrix}
0 & 0 \\
0 & 0
\end{bmatrix},
\begin{bmatrix}
0 & 0 \\
0 & 0
\end{bmatrix},
\begin{bmatrix}
0 & 0 \\
0 & 0
\end{bmatrix}
\]

and the sums are 5 for \(\alpha \in S_0\), 0 for \(\alpha \in S_1\), 2 for \(\alpha \in S_2\), showing that the new association relation \(\mathcal{A}\) is the two-class scheme with parameters

\[
v = 16,
\]

\[
n_1 = 5, \quad P_1 = \begin{bmatrix} 0 & 4 \\ 4 & 6 \end{bmatrix}, \quad P_2 = \begin{bmatrix} 2 & 3 \\ 3 & 6 \end{bmatrix}.
\]

\[
n_2 = 10,
\]

This is the Negative Latin Square type scheme \(NL_1(4)\). An isomorphic scheme is obtained by taking \(S_1 = \{1, 4\}\).

In Section 5, Theorem 4.8 will be applied to some schemes \(\mathcal{A}\) of the \(\mathcal{A}(v, \hat{m})\) family. Sums of elements of \(\hat{P}_\alpha\) in these schemes, \(\alpha = 2, \ldots, \hat{m}\), may be expressed as sums of elements of \(\hat{P}_1\) by suitable application of \((4.3)\). A rather simple consequence of \((4.3)\), stated as a lemma for later reference, is that the form of the set \(S_1\) can be partially specified without loss of generality.

Lemma 4.9. In applying Theorem 4.8 to a scheme \(\mathcal{A}(v, \hat{m})\) any set \(S_1\) satisfying \((4.26)\) is related by a cyclic permutation of the class indices.
1, 2, ..., \hat{n} to a set \{i_1, i_2, ..., i_m\} which satisfies (4.26) with the same p_{ll} and satisfies

\[ i_1 = 1 < i_2 < ... < i_m, \]

\[ i_2 - 1 \leq i_{t+1} - i_t, \quad t = 2, ..., m-1, \]

\[ i_2 - 1 \leq m+1 - i_m. \]

5. **Construction of NL_g schemes from finite fields.** This section will make use of some special cases of the association schemes \( \Upsilon(v,M) \) of Theorem 4.2. For \( n^2 \) a prime power, \( \Upsilon(n^2, n+1) \) will first be described for reference, then \( \Upsilon(n^2, n-1) \) will be used in the construction of some NL_g(n) schemes.

The multiplicative subgroup used in constructing \( \Upsilon(n^2, n+1) \) from \( GF(n^2) \) has \( n-1 \) elements, which along with the zero element are readily shown to form a subfield of order \( n \). Among the special features which follow from this are the following simple expressions for the parameters \( p^i_{jk} \) of \( \Upsilon(n^2, n+1) \).

(5.1)

\[ p^i_{ii} = n-2, \quad p^i_{jj} = p^i_{ij} = p^i_{ji} = 0, \quad p^i_{jk} = 1, \]

\[ i, j, k \text{ distinct}, \quad 1 \leq i, j, k \leq n+1. \]

Because of the uniformity of these values, this scheme lends itself exceptionally well to the formation of 2-class schemes by combination of associate classes. If Theorem 4.8 is applied with an arbitrary set \( S_1 \) of \( g \) of the indices 1, ..., \( n+1 \), condition (4.26) is satisfied and the resulting two-class scheme, in which \( n_1 = g(n-1) \), is of \( L_g(n) \) type. This turns out to be only a familiar construction in slightly disguised form. It can be shown that the \( n+1 \) associate classes in the scheme \( \Upsilon(n^2, n+1) \) are equivalent to the
n + 1 constraints of a complete set of pairwise orthogonal Latin squares of order n, a fact which will be taken up in Section 6 from the point of view of finite geometry. Consideration of Latin squares gives (5.1) at once and reduces the combination of associate classes to a simple application of the definition of the $L_g(n)$ scheme.

The scheme $\mathscr{S}(n^2, n-1)$ uses a multiplicative subgroup of order n+1 and has less regularity than $\mathscr{S}(n^2, n+1)$. In particular, the writer is unable to give general expressions for $p_{jk}^i$, though he conjectures that $0 \leq p_{jk}^i \leq 2$ for $1 \leq i, j, k \leq n-1$. However, there are analogies with the $\mathscr{S}(n^2, n+1)$ scheme and our success in combining $g$ associate classes of size $n-1$ to give a two-class scheme with $n_1 = g(n-1)$ suggests an attempt, with the $\mathscr{S}(n^2, n-1)$ scheme, to combine $g$ associate classes of size n+1 to give a two-class scheme with $n_1 = g(n+1)$, hopefully of negative Latin square type. It is not obvious that a set $S_1$ of $g$ indices can be found which meets condition (4.26) of Theorem 4.8, or that a two-class scheme if obtained will be of $NL_g$ type.

However, in the range $n < 10$ it is easy to write down the association schemes $\mathscr{S}(n^2, n-1)$ in sufficient detail that $p_{jk}^i$ values can be computed explicitly, and then to search empirically for suitable sets $S_1$. The results of this computation are given in tables which follow, and fortunately several schemes of $NL_g$ type are obtained, including the three new schemes $NL_3(8)$, $NL_2(9)$, $NL_3(9)$. It is not known whether the same method yields any $NL_g(n)$ schemes for $n > 10$.

The objects in all association schemes discussed in this section may be taken as elements of finite fields and will be represented in a notation which is convenient for field operations. The elements of $GF(p)$ for a prime
p will be denoted by the residues 0, 1, ..., p-1, and a polynomial of
degree at most q-1 with coefficients in GF(p) will be denoted briefly by the
q-tuple of its coefficients:

$$\sum_{i=0}^{q-1} a_i x^i = (a_{q-1}, \ldots, a_0) \equiv a_{q-1} \cdots a_0.$$

Under addition and multiplication modulo a polynomial Q(x) of degree q,
irreducible over GF(p), the polynomials \((a_{q-1}, \ldots, a_0)\) represent the field
GF(p^q). The polynomial Q will be chosen here so that a root \(\xi\) of \(Q(x) = 0\)
is a primitive element of GF(p^q). This will in general be possible for
more than one choice of the polynomial Q and the primitive element \(\xi\), and
while different choices lead to fields, and hence association schemes, which
are abstractly identical, the association schemes will differ by a permutation
of associate classes, as remarked in Section 4. For definiteness, the table
for each \(\mathbb{F}(n^2, n-1)\) will list the equation \(Q(\xi) = 0\) used in its construction.
Each table of powers of \(\xi\) will be arranged so that row 1 contains the set

$$\mathcal{C}_1 = \{\xi(n-1)u + 1, u = 0, 1, \ldots, n\}$$

of 1-th associates of the zero element in \(\mathbb{F}(n^2, n-1)\). The 1-th associates
of an element \(\theta\) are obtained by adding \(\theta\) to each of the 1-th associates of
zero. The matrix \(P_1\) exhibits the parameters \(p_{jk}^1\), which are calculated by
means of (4.4); it follows from (4.3) that the matrices \(P_2, \ldots, P_{n-1}\) may
be obtained from \(P_1\) by cyclic permutation of rows and columns.

It may be verified by straightforward calculation that each set
\(S_1 = \{i_1, i_2, \ldots, i_g\}\) listed for an NL_(1) (n) scheme meets condition (4.26)
with the appropriate values of \(p_{1,1}^1\). In the NL_g(n) scheme, the first
associates of the zero object are the elements in rows \(i_1, i_2, \ldots, i_g\) of the table of powers of \(\xi\), and the first associates of \(\theta\) are obtained by adding \(\theta\) to the first associates of zero. The search by trial and error for the sets \(S_1\) was the only part of the construction method which was tentative as well as tedious. It was expedited by restricting \(S_1\) to the form described in Lemma 4.9. The search was exhaustive and the author can report for each \(\gamma(n^2, n-1)\) scheme considered, that the sets \(S_1\) listed, other sets obtained from them by cyclic permutation of the indices \(1, 2, \ldots, n\), and the complements of these sets, are the only sets of associate classes which can be combined to give two-class association schemes.

The methods of this section base on finite fields thus fail to provide constructions for the schemes \(NL_2(7)\) and \(NL_2(8)\), or to give any new schemes not of the \(NL_g\) family in the range \(v \leq 100\). The attempt to construct \(NL_2(7)\) from \(\gamma(49, 6)\) was supplemented by attempts with other \(\gamma(v, m)\) schemes, such as \(\gamma(49, 12)\), in which combination of classes could give two associate classes of sizes \(n_1 = 16, n_2 = 32\), but condition (4.26) was not satisfied in any case.

The following two-class schemes may be obtained by combining associate classes in $S(9^2, 8)$.

- **NL$_2$(9)**, a new scheme. $S_1 = \{1, 5\}$.
- **NL$_3$(9)**, a new scheme. $S_1 = \{1, 2, 7\}$.
- **NL$_4$(9)**, a known scheme. $S_1 = \{1, 3, 5, 7\}$ or $\{1, 2, 5, 6\}$. 
To illustrate the computation of the matrix $P_{1}$ for $\mathcal{G}(v, m)$ schemes, we evaluate some of the values $p^{1}_{jk}$ for $\mathcal{G}(5^2, 4)$. We recall that if the unit element, 01 in this example, is added to each element of $\mathcal{C}_{k} = \{a_{k, u}, u = 0, 1, \ldots, n\}$, the resulting set contains exactly $p^{1}_{jk}$ elements of $\mathcal{G}_{j}$. The following working table is so arranged that $p^{1}_{jk}$ is given by the number of columns which contain $k$ in the first row and $j$ in the last row.

\[
\begin{array}{l|cccccccccc}
  k & 1 & 1 & 1 & 1 & 1 & 1 & 2 & 2 & 2 & 2 \\
  u & 0 & 1 & 2 & 3 & 4 & 5 & 0 & 1 & 2 & 3 & 4 & 5 \\
  a_{k, u} & 01 & 22 & 21 & 04 & 33 & 34 & 10 & 41 & 31 & 40 & 14 & 24 \\
  a_{k, u} + 01 & 02 & 23 & 22 & 00 & 34 & 30 & 11 & 42 & 32 & 41 & 10 & 20 \\
  j \ni a_{k, u} + 01 \in \mathcal{G}_{j} & 3 & 4 & 1 & - & 1 & 4 & 3 & 3 & 4 & 2 & 2 & 4 \\
\end{array}
\]

Tabulation of the results gives

\[
\begin{array}{l|cccc}
  k & 1 & 1 & 1 & 2 \\
  j & 1 & 2 & 3 & 4 \\
  p^{1}_{jk} & 0 & 1 & 2 & 0 & 2 & 2 & 2 \\
\end{array}
\]

6. Geometric interpretations of $\mathcal{G}(v, m)$ association schemes. The finite field scheme $\mathcal{G}(n^2, n+1)$ furnishes an easy construction of a finite Euclidean plane geometry of order $n$. The $n^2$ objects of the association scheme are interpreted as points of this geometry. It is easy to show that lines satisfying the incidence postulates of the geometry are obtained by defining as a line every set consisting of a point and its $n-1$ $i$-th associates, $i = 1, \ldots, n+1$. In particular, there are $n^2 + n$ lines, each containing $n$ points. For fixed $i$, the points fall into $n$ pairwise disjoint lines, which comprise a parallel class. The geometry obtained for any $n$
(of prime power form) is the unique Desarguesian plane.

We remark that if \( v = n^k, t \) is a divisor of \( k \), and \( N = n^{t-1} \), so that 
\[
m = (v-1)/N = n^{k-t} + n^{k-2t} + \ldots + 1,
\]
then the association scheme \( \mathcal{A}(v, m) \) may be used to generate some of the \( t \)-dimensional subspaces in \( \text{EG}(k, n) \), the Euclidean geometry of dimension \( k \) and order \( n \), giving all such subspaces (lines) in the case \( t = 1 \).

Conversely, in the case \( t = 1 \), a finite Euclidean geometry may be used to construct association schemes \( \mathcal{A}(n^k, m) \), where \( n_i = N = (n^{k-1})/m = n-1 \). Associate classes are identified with the \( m \) parallel classes of lines and the \( i \)-th associates of a point are the points which occur with it on a line of the \( i \)-th parallel class. In the case \( k = 2 \) of a plane geometry, the Desarguesian plane gives an \( \mathcal{A}(n^2, n+1) \) scheme while a non-Desarguesian plane gives a pseudo- \( \mathcal{A}(n^2, n+1) \) scheme, which has the same parameters \( n_i, \ p_{jk} \) but whose elements do not correspond to those of \( \mathcal{A}(n^2, n+1) \) under any one-one mapping which preserves the association relation.

In the \( L_2(n) \) scheme which is obtained from \( \mathcal{A}(n^2, n+1) \) by class combination, the set of first associates of an object can now be interpreted as a simple geometric figure. Some \( g \) of the parallel classes are chosen—speaking informally, \( g \) of the directions on the plane. The first associates of a point \( \theta \) are the remaining points on the lines through \( \theta \) in the \( g \) chosen directions.

Retaining the identification of the elements of \( GF(n^2) \) with the points of \( \text{EG}(2, n) \), we turn to the association scheme \( \mathcal{A}(n^2, n+1) \) and ask what geometric figure is formed by the \( n+1 \) \( i \)-th associates of a point \( \theta \).

As \( i \) ranges over the values 1, ..., \( n-1 \), a collection of \( n-1 \) disjoint figures is obtained which exhausts the \( n^2-1 \) points of the plane other than \( \theta \).
In an NLg(n) scheme formed by combining g associate classes, the set of first associates of θ will be the union of g of these geometric figures.

**DEFINITION.** For θ ∈ GF(n^2), C_i(θ) will denote the set of i-th associates of θ in θ(n^2, n+1) and C_i(θ) will denote the set of i-th associates of θ in θ(n^2, n-1).

**Theorem 6.1.** The number of elements in C_i(θ) ∩ C_j(θ) is

1 if n is even,
2 if n is odd and i ≡ j (mod 2),
0 if n is odd and i ≠ j (mod 2).

**Proof.**

C_i(θ) = \{θ + g(n+1)u + i-1, u = 0, ..., n-2\}.

C_j(θ) = \{θ + g(n-1)w + j-1, w = 0, ..., n\}.

The number of elements common to these sets is the number of pairs u, w of integers in the specified ranges for which

θ + g(n+1)u + i-1 = θ + g(n-1)w + j-1.

This equation is equivalent to

(6.1) (n + 1)u + i-1 = (n-1)w + j-1 = y-1, say,

which in turn is equivalent to

(6.2) 0 < y ≤ n^2 - 1,

y ≡ i (mod (n+1)),

y ≡ j (mod (n-1)).

Methods of elementary number theory applied either to the Diophantine equation (6.1) or the congruences (6.2) show that if d = (n+1, n-1), the greatest
common divisor of \( n+1 \) and \( n-1 \), then the number of solutions is \( d \) if \( i \equiv j \) \((\text{mod } d)\) and is zero otherwise. If \( n \) is even, \( d = 1 \); if \( n \) is odd, \( d = 2 \); the conclusion of the theorem follows at once.

This theorem shows that if \( \theta \) is a point of \( E(2,n) \) and if \( n \) is even, then the points of each set \( \mathcal{C}_j(\theta) \) are distributed one each over the lines on \( \theta \). If \( n \) is odd, the points of \( \mathcal{C}_j(\theta) \) are distributed two each over half the lines on \( \theta \). The next theorem gives a deeper insight.

**Theorem 6.2.** For any \( \theta \in \text{GF}(n^2) \), and for any \( i, j, 1 \leq i \leq n-1, 1 \leq j \leq n+1 \), no three elements of \( \mathcal{C}_i(\theta) \) are pairwise \( j \)-th associates in \( \text{GF}(n^2, n+1) \).

**Remarks.** In terms of the \( E(2,n) \) induced by the scheme \( \mathcal{G}(n^2, n+1) \), this theorem says that no three points of a set \( \mathcal{C}_i(\theta) \) are collinear. We are in the fortunate position of having three methods of proof of this theorem, of which all are instructive and two will be given here. These two proofs use the following well-known facts on finite fields. For \( x \in \text{GF}(n^2) \), \( x^{n^2} = x \). Also, the mapping \( x \rightarrow x^n \) is an automorphism of \( \text{GF}(n^2) \) which reduces to the identity \( x^n = x \) if and only if \( x \in \text{GF}(n) \).

**Proof I.** Three distinct elements of \( \mathcal{C}_i(\theta) \) may be represented

\[
(6.3) \quad \varphi_t = \theta + \xi^{u_t(n-1) + 1-l}, \quad t = 1, 2, 3,
\]

where \( \xi \) is a primitive element of \( \text{GF}(n^2) \) and \( u_1, u_2, u_3 \) are distinct modulo \( n + 1 \). It will be convenient to use the abbreviation

\[
(6.4) \quad \eta_t = \xi^{u_t(n-1)}.
\]

\( \eta_1, \eta_2, \eta_3 \) are nonzero elements which are distinct since \( \varphi_1, \varphi_2, \varphi_3 \) are distinct.
The representation we are using for the geometry has the property that \( \varphi_1, \varphi_2, \varphi_3 \), regarded as points, are collinear if and only if, regarded as elements of \( GF(n^2) \), they satisfy an equation

\[
(6.5) \quad a_1 \varphi_1 + a_2 \varphi_2 + a_3 \varphi_3 = 0 ,
\]

where \( a_1, a_2, a_3 \), not all zero, are elements of the subfield \( GF(n) \), and

\[
(6.6) \quad a_1 + a_2 + a_3 = 0 .
\]

Using (6.3), (6.4) and (6.6) and simplifying, we find that (6.5) is equivalent to

\[
(6.7) \quad a_1 \eta_1 + a_2 \eta_2 + a_3 \eta_3 = 0 .
\]

Since the mapping \( x \to x^n \) is an automorphism, a valid equation is obtained if it is applied to all the field elements in equation (6.7). Under the mapping, each of \( a_1, a_2, a_3 \), 0 maps into itself, \( \xi^n = \xi^{n-1} \) maps into \( \xi^{u_n(1-n)} = \xi^{u_n(1-n)} \), and \( \eta_t \) accordingly maps into \( \eta_t^{-1} \). The new equation is

\[
(6.8) \quad a_1 \eta_1^{-1} + a_2 \eta_2^{-1} + a_3 \eta_3^{-1} = 0 .
\]

The system of equations (6.6), (6.7), (6.8) in \( a_1, a_2, a_3 \) has determinant of coefficients

\[
\begin{vmatrix}
1 & 1 & 1 \\
\eta_1 & \eta_2 & \eta_3 \\
\eta_1^{-1} & \eta_2^{-1} & \eta_3^{-1}
\end{vmatrix} \quad = \quad \eta_1^{-1} \begin{vmatrix}
\eta_1 & \eta_2 & \eta_3 \\
\eta_1^{-1} & \eta_2^{-1} & \eta_3^{-1} \\
1 & 1 & 1
\end{vmatrix} = \eta_1^{-1} \eta_2^{-1} \eta_3^{-1} (\eta_1^{-1} \eta_2)(\eta_2^{-1} \eta_3)(\eta_3^{-1} \eta_1). 
\]
Since $\eta_1$, $\eta_2$, $\eta_3$ are distinct, the determinant is nonzero and the system has no nontrivial solution $a_1$, $a_2$, $a_3$. Then $\varphi_1$, $\varphi_2$, $\varphi_3$ are not collinear.

Proof I is complete.

Proof II. We need the fact that for $z \in \text{GF}(n^2)$, $z^n + z$ is an element of the subfield $\text{GF}(n)$. The proof is that under the automorphism $x \rightarrow x^n$, this element maps into itself.

$$z^n + z \rightarrow z^2 + z^n = z + z^n.$$ 

The elements $\varphi = \varphi(w)$ of $C_1(\theta)$ may be expressed

$$(6.9) \quad \varphi = s^{i-1} \beta^w, \quad w = 0, \ldots, n,$$

where $\beta = s^{n-1}$. Let $\varphi_0 = \theta + s^{i-1} \beta^0$ and $\varphi$ be distinct elements of $C_1(\theta)$, where $(6.9)$ determines a value $w \neq w_0$ corresponding to $\varphi$. Then $\varphi$ and $\varphi_0$ are $j$-th associates in scheme $z(n^2, n+1)$ for some value of $j$, which we now determine. That is, we find $j$ so that $\varphi - \varphi_0$ can be expressed in the form $s^{j-1} \alpha^u$, where $\alpha = s^{n+1}$.

$$\varphi - \varphi_0 = (\varphi - \theta) - (\varphi_0 - \theta) = s^{i-1} \beta^w - s^{i-1} \beta^0.$$ 

Now $-1 = \beta^c$, where

$$c = \frac{1}{2}(n + 1) \text{ if } n \text{ is odd},$$

$$c = 0 \text{ if } n \text{ is even}.$$ 

$$\varphi - \varphi_0 = s^{i-1} \beta^w + s^{i-1} \beta^{w_0+c}$$

$$= s^{i-1} + nw - w + s^{i-1} + n(w_0 + c) - (w_0 + c)$$

$$= s^{i-1} + n(w_0 + c - w) [s^n(w - w_0 - c) + s^w - w_0 - c].$$
The factor in brackets is an element of $GF(n)$ since it is of the form $z^n + z$, and is nonzero since $\varphi \neq \varphi_0$. It may therefore be expressed $\alpha^u$ for some $u$. Then

$$\varphi - \varphi_0 = \xi^i - 1 + n(w_0 + c) - w \cdot \alpha^u,$$

determining that $\varphi$ and $\varphi_0$ are $j$th associates in $\gamma(n^2, n+1)$ for $1 \leq j \leq n+1$,

(6.10) \hspace{1cm} j \equiv i + n(w_0 + c) - w \pmod{n + 1}).

As $\varphi$ ranges over $C_i(\theta)$, $\varphi \neq \varphi_0$, $w$ ranges over distinct values $0$, $1$, ..., $n$, $w \neq w_0$. Clearly the corresponding values of $j$ are distinct. Thus no two elements of $C_i(\theta)$ are common $j$th associates of $\varphi_0$ for any $j$, where $\varphi_0$ is an arbitrary element of $C_i(\theta)$. This implies the conclusion of the theorem and completes Proof II.

An oval in a finite plane of order $n$ is defined as a set of $n + 1$ points, $n$ odd, or $n + 2$ points, $n$ even, with the property that no three points of the set are collinear. It is known that an oval is a maximal set with this property. In the EG$(2,n)$ generated by $\gamma(n^2, n-1)$, let $\theta$ be any point and let $i = 1, 2, ..., n-1$. Theorem 6.2 shows for $n$ odd that $C_i(\theta)$ is an oval. Theorems 6.2 and 6.1 show for $n$ even that $\{\theta\} \cup C_i(\theta)$ is an oval.

The $n + 1$ points of a non-degenerate conic in PG$(2,n)$ furnish an example of an oval when $n$ is odd.

A non-degenerate conic in PG$(2,n)$, $n = 2^t$, has the property that its $n + 1$ tangent lines are concurrent in an $(n + 2)$nd point which together with the points of the conic makes up an oval. It has been shown by Segre [20] that in the Desarguesian projective plane of odd order $n$, every oval
is a conic. In particular, this holds for every oval in a Desarguesian Euclidean plane of odd order $n$. The $EG(2,n)$ constructed from $\mathbb{F}(n^2, n+1)$ is Desarguesian. Therefore for $n$ odd, the $n-1$ sets $C_i(\theta)$ for any element $\theta$ are conics, pairwise disjoint, all confined to the Euclidean plane (and thus disjoint from the "line at infinity"), all disjoint from the point $\theta$ and with it exhausting the $n^2$ points of the plane.

It is plausible conjecture that the scheme $\mathbb{F}(n^2, n-1)$ for $n = 2^t$ also leads to sets $C_i(\theta)$ which are conics, and this has been verified for $n = 4$ and $n = 8$. Segre's proof does not investigate ovals for even $n$.

Without giving details, we state that these conics can be exploited to give information on $\mathbb{F}(n^2, n-1)$. The algebraic statements that $C_i(\theta)$ is a multiplicative subgroup in $GF(n^2)$, each $C_i(\theta)$ is a coset, and each $C_i(\theta)$ is obtained by addition, all have implications for the equations of the conics. Each $p^i_{jk}$ can be interpreted as the number of points of intersection of two conics. We conjecture that this will lead to a proof that $0 \leq p^i_{jk} \leq 2$.

After the author conjectured that the sets $C_i(\theta)$ were conics, the first proof of Theorem 6.2 was found by R. C. Bose. Using some ideas from this proof, the author then devised the second proof. While these were the first premeditated proofs, a third method became available when R. H. Bruck noticed that the configuration of $n-1$ disjoint conics in the Euclidean plane of order $n$ could be obtained in many ways by taking suitable plane sections of a configuration he had already discovered in the projective 3-space of order $n$, consisting of two lines and $n-1$ ruled quadrics, all disjoint and exhausting the points of the space. The details, which will not be given here, are part of the theory of spreads in projective space [10].
The NL$_g(n)$ schemes obtained in Section 5 by combination of associate classes now inherit a geometric interpretation: the set of first associates of a point $\theta$ is the union of $g$ "concentric" conics about $\theta$. Unfortunately, neither the algebraic construction nor the geometric representation has enabled the author to determine in general which NL$_g(n)$ schemes can be formed from $\psi(n^2, n-1)$ schemes. The case $n = 2m + 1$, $g = m$ is rather special and is discussed in the following paragraph.

As noted in Section 2, the NL$_m(2m + 1)$ scheme, the L$_{m+1}(2m+1)$ scheme, and the pseudo-cyclic scheme with $v = (2m + 1)^2$ all have the same parameters. The scheme $\psi((2m + 1)^2, 2)$ is pseudo-cyclic; it is identical with the L$_{m+1}(2m+1)$ scheme obtained from $\psi((2m + 1)^2, 2m + 2)$ by combining the set $S_1 = \{1, 3, \ldots, 2m + 1\}$ of associate classes; it is also identical with the NL$_m(2m + 1)$ scheme obtained from $\psi((2m + 1)^2, 2m)$ by combining the set $S_1 = \{1, 3, \ldots, (2m-1)\}$ of associate classes. Geometrically, the set of first associates of a point $\theta$ appears first as the union of half of the $2m + 2$ lines through $\theta$ (with $\theta$ deleted), and second as the union of half of the $2m$ conics $C_1(\theta)$. Even in this special case there are association schemes with the same parameters but with less geometric regularity. The L$_m(2m + 1)$ scheme can be constructed using an arbitrary set $S_1$ of $m + 1$ associate classes, giving each point $\theta$ a set of first associates which is a union of lines through $\theta$ but not in general a union of conics $C_1(\theta)$. At least one negative Latin square construction, NL$_4(9)$ using $S_1 = \{1, 2, 5, 6\}$, gives $\theta$ a set of first associates which is a union of conics $C_1(\theta)$ but not of lines. Two solutions of the pseudo-cyclic scheme for a given $n$ may be identical as association schemes in spite of differences in geometric structure; that is, they may be related by a one-one correspondence of objects which preserves the
association relation without preserving algebraic or geometric relationships.

Thus even in simple cases our geometric interpretation of negative Latin square association schemes needs some clarification. It will probably be of interest to make a geometrical investigation of \( \gamma(v,m) \) schemes other than those that have been employed here.

7. **Direct construction of NL designs from finite geometries.** A design with the negative Latin square association scheme \( NL_2(8) \) occurs as the case \( s = 4 \) of a family of two-class designs with parameters

\[
(7.1) \quad v = s^3, \quad s = 2^t,
\]

\[
n_1 = (s + 2)(s - 1),
\]

\[
p_{11}^1 = s - 2,
\]

\[
p_{11}^2 = s + 2,
\]

\[
r = s + 2,
\]

\[
k = s,
\]

\[
\lambda_1 = 1,
\]

\[
\lambda_2 = 0,
\]

constructed by Ray-Chaudhuri [19]. The construction uses \( PG(3,s) \), the projective 3-space of order \( s, s = 2^t \), in which there are \( s + 1 \) points on each line, \( s^2 + s + 1 \) points on each plane, and \( s^3 + s^2 + s + 1 \) points in all. In one plane \( \gamma \) a non-degenerate conic \( Q \) is chosen. Each of the \( s + 1 \) points of \( Q \) is on one line of \( \gamma \) which contains no other points of \( Q \) and is called a tangent line. A special property of planes of even order is that the tangents of a conic are all concurrent in a point \( P \). Let \( R \) be the set \( Q \cup \{P\} \), containing \( s + 2 \) points of \( \gamma \). The \( s^3 \) points not on \( \gamma \) are taken as
objects in the design, and two of these points are first associates if and only if the line containing them also contains a point of \( R \). All such lines, with the points of \( R \) deleted, are the blocks of the design. The parameters are immediate with the exception of \( p_1^{11} \) and \( p_1^{22} \), which follow from certain properties of conics.

There is no value of \( s = 2^t \) other than 4 for which the design of the Ray-Chaudhuri family is of \( NL_g \) type, but we shall describe a generalization which leads to infinitely many \( NL_g \) designs, among others. This generalization seems to have gone unnoticed until now.

Various known theorems and formulas in finite geometry, which have been adapted from [25] and from Chapter 2 of [2], will be stated as needed without further reference. The number of elements in a finite set \( S \) will be denoted by \( |S| \).

Let \( \Sigma = PG(n,s) \) be a projective space of dimension \( n \) and order \( s \), where \( s \) is a prime power. Let \( \Gamma = PG(n-1,s) \) be a fixed subspace of dimension \( n - 1 \), and let \( \Delta \) be the complement of \( \Gamma \) in \( \Sigma \). A set \( R \) of points of \( \Gamma \) is chosen. \( \bar{R} \) denotes the complement of \( R \) in \( \Gamma \). \( \Delta \) contains \( s^n \) points, which are taken as the objects in a two-class design \( g(R) \). Each line not entirely in \( \Gamma \) contains \( s \) points of \( \Delta \) and one point of \( \Gamma \). Two points of \( \Delta \) are taken as first associates if and only if the line joining them contains a point of \( R \). All such lines, with the points of \( R \) deleted, are the blocks of \( g(R) \).

Clearly,
(7.2) \[ v = s^n, \]
\[ n_1 = (s - 1) |R|, \]
\[ r = |R|, \]
\[ k = s, \]
\[ b = s^{n-1} |R|, \]
\[ \lambda_1 = 1, \]
\[ \lambda_2 = 0. \]

\( \gamma(R) \) will be partially balanced if and only if condition (iii) of (1.3) is satisfied. We proceed to interpret this as a condition on the set \( R \).

If \( A \) and \( B \) are two points of \( \Lambda \) which are \( i \)-th associates, \( i = 1, 2 \), we denote by \( \Pi_i(A, B) \) the number of points \( C \) which are common first associates of \( A \) and \( B \). The required points \( C \) are of two types which will be enumerated separately.

**DEFINITION.** \( D \) is the point of \( \Gamma \) on line \( AB \). Let \( C \) be a common first associate of \( A \) and \( B \). Then we define \( C \) to be a collinear common first associate of \( A \) and \( B \) (c-point of \( A \) and \( B \)) if \( C \) is on line \( AB \), and a diagonal common first associate of \( A \) and \( B \) (d-point of \( A \) and \( B \)) if \( C \) is not on line \( AB \).

Obviously there are \( s - 2 \) c-points of \( A \) and \( B \) if \( D \in R \) and none if \( D \in \bar{R} \).

If \( C \) is a d-point of \( A \) and \( B \), then lines \( AC \) and \( BC \) respectively must meet \( \Gamma \) in points \( D' \) and \( D'' \) of \( R \). Plane \( ABC \) meets \( \Gamma \) in a line \( m \) on \( D \) which also contains \( D' \) and \( D'' \). Suppose that \( m \) contains \( \nu \) points of \( R \). Then the ordered pair of points \( D', D'' \) can be chosen in \( (\nu - 1)(\nu - 2) \) ways if \( D \in R \),
and in \(v(v-1)\) ways if \(D \in \bar{R}\), and the plane determined by \(m\), \(A\) and \(B\) contains a like number of \(d\)-points of \(A\) and \(B\). The total number of \(d\)-points of \(A\) and \(B\) can be obtained by summing over the lines \(m\) which are in \(\Gamma\) and contain \(D\).

**DEFINITION.** \(T_\nu(R)\) is the set of lines of \(\Gamma\) which contain exactly \(\nu\) points of \(R\), \(\nu = 0, 1, \ldots, s+1\).

**DEFINITION.** \(x_\nu(D), \nu = 0, 1, \ldots, s+1\), is the number of lines of \(T_\nu(R)\) which contain \(D\).

Now if \(A\) and \(B\) are first associates, so that \(D \in R\),

\[
(7.3) \quad p_{11}^1(A,B) = s - 2 + \sum_{\nu=0}^{s+1} (\nu - 1)(\nu - 2) x_\nu(D),
\]

and if \(A\) and \(B\) are second associates, so that \(D \in \bar{R}\),

\[
(7.4) \quad p_{11}^2(A,B) = \sum_{\nu=0}^{s+1} \nu(\nu - 1) x_\nu(D).
\]

This is enough to prove

**LEMMA 7.1.** \(\xi(R)\) is a two-class PBIB design if and only if the right hand side of (7.3) has the same value for all points \(D \in R\) and the right hand side of (7.4) has the same value for all points \(D \in \bar{R}\). In this case \(\xi(R)\) will have parameters (7.2), along with

\[
p_{11}^1 = p_{11}^1(A,B), \quad p_{11}^2 = p_{11}^2(A,B).
\]

**REMARK.** The condition of Lemma 7.1 will be recognized as essentially a condition on the variance of the numbers \(\nu\). It is implied by the condition the following lemma places on their frequency distribution.
LEMMA 7.2. \( \mathcal{L}(R) \) is a two-class PBIB design if for fixed \( v = 0, 1, \ldots, s+1 \), the frequencies \( x_v(D) \) are equal for all \( D \in R \) and are equal for all \( D \in \overline{R} \). In this case \( \mathcal{L}(R) \) will have parameters as stated in Lemma 7.3.

In our first application of these lemmas we take \( R = Q \), a non-degenerate quadric in \( \Gamma = \text{PG}(n-1,s) \), denoting \( \overline{Q} = \overline{R} \). All lines of \( \Gamma \) fall into the following four sets \( T_v(Q) \).

\[
\begin{align*}
T_0(Q) & : \text{non-intersectors, containing no points of } Q, \\ 
T_1(Q) & : \text{tangents, each containing 1 point of } Q, \\ 
T_2(Q) & : \text{secants, each containing 2 points of } Q, \\ 
T_{s+1}(Q) & : \text{rulings, each containing } s+1 \text{ points of } Q.
\end{align*}
\]

Thus nonzero frequencies \( x_v(D) \) can occur only for \( v = 0, 1, 2, s+1 \), and (7.3) and (7.4) reduce to

\[
\begin{align*}
(7.6) & \quad p_{11}^1(A,B) = s - 2 + s(s - 1) x_{s+1}(D), \quad D \in Q, \\
(7.7) & \quad p_{11}^2(A,B) = 2 x_2(D), \quad D \in \overline{Q}.
\end{align*}
\]

In a particular non-degenerate quadric \( Q \) in \( \text{PG}(n-1,s) \), the number \( x_{s+1}(D) \) of rulings on \( D \) is the same for all points \( D \in Q \), so that \( p_{11}^1(A,B) \) has a uniform value \( p_{11}^1 \) for all pairs \( A, B \) of first associates in \( \mathcal{L}(Q) \).

We must specify the dimension \( n \) before proceeding further. If \( n = 2t \), so that \( \Gamma \) has odd dimension \( 2t-1 \), the number \( x_2(D) \) of secant lines on \( D \) is the same for all points \( D \in \overline{Q} \), so that \( p_{11}^2(A,B) \) has a uniform value \( p_{11}^2 \) for all pairs \( A, B \) of second associates in \( \mathcal{L}(Q) \). If \( n \) is odd, so that \( Q \) is a non-degenerate quadric in a space \( \Gamma \) of even dimension, the points \( D \in \overline{Q} \) are of different types which are contained in different numbers \( x_2(D) \) of secant
lines. In this case \( p_{ll}^2(A,B) \) does not have the same value for all pairs \( A, B \) of second associates.

We conclude that if \( Q \) is a non-degenerate quadric in \( \Gamma \), the design \( \mathcal{G}(Q) \) is a two-class partially balanced design if and only if the dimension \( n \) of \( \Sigma \) is even.

Let \( n = 2t \). In \( \Gamma = PG(2t-1,s) \) there are two types of non-degenerate quadrics, which we shall call hyperbolic and elliptic, differing in the number of points, ruling lines, and secants. In the following formulas, the upper signs hold for hyperbolic quadrics and the lower signs hold for elliptic quadrics.

\[
(7.8) \quad |Q| = (s^{t-1} + 1)(s^t - 1)/(s - 1),
\]

\[
x_{s+1}(D) = (s^{t-2} + 1)(s^{t-1} + 1)/(s - 1), \quad D \in Q,
\]

\[
x_2(D) = s^{t-1}(s^{t-1} + 1)/2, \quad D \in \overline{Q}.
\]

The parameters of \( \mathcal{G}(Q) \) can now be computed in both cases and compared with (2.1) and (2.5) to complete the proof of

THEOREM 7.1. If \( n = 2t \) and \( Q \) is a non-degenerate quadric in \( \Gamma \), the design \( \mathcal{G}(Q) \) is a two-class PBIB design with association scheme parameters

\[
(7.9) \quad v = s^{2t},
\]

\[
\lambda_1 = (s^{t-1} + 1)(s^t - 1),
\]

\[
\lambda_2 = s^{t-1}(s^{t-1} + 1) + s^t - 2,
\]

\[
p_{ll}^2 = s^{t-1}(s^{t-1} + 1),
\]
and design parameters

\[(7.10) \quad r = (s^{t-1} + 1)(s^t + 1)/(s - 1),\]

\[k = s,\]

\[b = s^{2t-1} r,\]

\[\lambda_1 = 1,\]

\[\lambda_2 = 0.\]

If \(Q\) is hyperbolic the upper signs hold and \(S(Q)\) is of pseudo-Latin square type \(L_g(s^t), g = s^{t-1} + 1\). If \(Q\) is elliptic the lower signs hold and \(S(Q)\) is of negative Latin square type \(NL_g(s^t), g = s^{t-1} - 1\).

Since the required projective spaces and quadrics exist for every \(s\) which is a prime or a power of a prime and for every positive integer \(t\), our construction gives a doubly infinite family of designs having \(NL_g\) association schemes. The following schemes with \(v \leq 100\) are included.

\[s = 2, \ t = 2, \ NL_1(4),\]

\[s = 2, \ t = 3, \ NL_3(8),\]

\[s = 3, \ t = 2, \ NL_2(9).\]

The spaces \(\Sigma, \Gamma, \Delta\) and the quadric \(Q\) may be used to construct other designs which have the same association scheme as \(S(Q)\).

We note that each block of \(S(Q)\) is the intersection \(\ell \cap \Delta\) of \(\Delta\) with a line \(\ell\) of \(\Sigma\), where \(\ell\) intersects \(\Gamma\) in a point of \(Q\). We define a more general design \(S_\nu(Q), \nu = 0, 1\), with sets of blocks constructed as follows from the set of all lines \(\ell\) which are in \(\Sigma\) but not in \(\Gamma\).
<table>

<td>${ \pi \cap \Delta \mid \pi \cap \Gamma \in Q }$</td>
</tr>
</tbody>
</table>

The subscript $\nu$ may be interpreted as the number of points of $Q$ contained in $\pi$. The following theorem is now obvious.

**THEOREM 7.2.** If $n = 2t$ and $Q$ is a non-degenerate quadric in $\Gamma$, then $L_{\nu}(Q)$, $\nu = 0, 1$, is partially balanced with the same association scheme as $L(Q)$ described in Theorem 7.1. $L_{\nu}(Q)$ has association scheme parameters $(7.5)$. $L_1(Q)$ is identical with $L(Q)$. $L_0(Q)$ has design parameters

\[(7.11) \quad r = |\overline{Q}|,\]
\[k = s,\]
\[b = s^{2t-1} |\overline{Q}|,\]
\[\lambda_1 = 0,\]
\[\lambda_2 = 1.\]

Let $\pi$ be a plane in $\Sigma$ but not in $\Gamma$. $\pi$ intersects $\Delta$ in a set of $s^2$ points which we shall use as a block of a design, and intersects $\Gamma$ in a line which falls in one of the classes $T_{\nu}(Q)$. We define designs $P_{\nu}(Q)$ with sets of blocks constructed as follows from the set of all planes $\pi$ which are in $\Sigma$ but not in $\Gamma$.

<table>
<thead>
<tr>
<th>Design</th>
<th>Blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_{\nu}(Q)$</td>
<td>${ \pi \cap \Delta \mid \pi \cap \Gamma \in T_{\nu}(Q) }, \quad \nu = 0, 1, 2, s + 1.$</td>
</tr>
</tbody>
</table>
The subscript $\nu$ may be interpreted as the number of points of $Q$ contained in $\pi$.

If $A$ is a point of $\Delta$, planes containing $A$ are determined by the lines of $T_{\nu}(Q)$, and these planes lead to the blocks of $P_{\nu}(Q)$ which contain $A$. Therefore $A$ is contained in $|T_{\nu}(Q)|$ blocks.

If $A$ and $B$ are two points of $\Delta$ and $D$ is the intersection of line $AB$ with $\Gamma$, planes containing $A$ and $B$ are determined by the lines of $T_{\nu}(Q)$ which contain $D$, and these planes lead to the blocks of $P_{\nu}(Q)$ which contain both $A$ and $B$. Therefore $A$ and $B$ occur together in $x_{\nu}(D)$ blocks. We now use the fact, stated in part in (7.8), that for a non-degenerate $Q$ in $\Gamma$ of odd dimension, all of the frequencies $x_{\nu}(D)$ satisfy the uniformity condition of Lemma 7.2. This gives us the following theorem.

**Theorem 7.3.** If $n = 2t$ and $Q$ is non-degenerate, then $P_{\nu}(Q)$, $\nu = 0, 1, 2, s+1$, is partially balanced with the same association scheme as $\tau(Q)$, described in Theorem 7.1. $P_{\nu}(Q)$ has association scheme parameters (7.9) and design parameters

\[(7.12) \quad r = T_{\nu}(Q),\]
\[k = s^2,\]
\[b = s^{2t-2} |T_{\nu}(Q)|,\]
\[\lambda_1 = x_{\nu}(D), \quad D \in Q,\]
\[\lambda_2 = x_{\nu}(D), \quad D \in Q.\]

Formulas for $|T_{\nu}(Q)|$ and $x_{\nu}(D)$ are listed below. In each case $Q$ is understood to be a non-degenerate quadric in $\Gamma = PG(2t-1, s)$. The upper signs hold if $Q$ is hyperbolic and the lower signs hold if $Q$ is elliptic.
### TABLE 7.1

| \(v\) | \(|T_v(q)|\) | \(x_v(D), D \in \mathbb{Q}\) | \(x_v(D), D \in \overline{\mathbb{Q}}\) |
|---|---|---|---|
| 0 | \(\frac{s^{2t-2}(s^t + 1)(s^{t-1} + 1)}{2(s+1)}\) | 0 | \(\frac{s^{t-1}(s^{t-1} + 1)}{2}\) |
| 1 | \(\frac{s^{t-2}(s^{2t-2} - 2)(s^t + 1)}{s-1}\) | \(s^{t-2}(s^{t-1} + 1)\) | \(\frac{s^{2t-2} - 1}{s - 1}\) |
| 2 | \(\frac{s^{2t-2}(s^t + 1)(s^{t-1} + 1)}{2(s - 1)}\) | \(s^{2t-2}\) | \(\frac{s^{t-1}(s^{t-1} + 1)}{2}\) |
| s+1 | \(\frac{(s^{2t-2} - 1)(s^t + 1)(s^{t-2} + 1)}{(s^2 - 1)(s - 1)}\) | \(\frac{(s^{t-1} + 1)(s^{t-2} + 1)}{s - 1}\) | 0 |

There are sets \(R\) other than quadrics for which the design \(\xi(R)\) is partially balanced, as illustrated by the Ray-Chaudhuri family of designs described at the beginning of the section. Our final construction uses an interesting set whose properties have been investigated by Bose [1].

Take \(\Sigma = \text{PG}(2,q)\), \(\Gamma = \text{PG}(2,q)\), where \(q = s^2\), and represent the points of \(\Gamma\) by homogeneous coordinates \((y_1, y_2, y_3)\), \(y_i \in \text{GF}(q)\). Take \(R = W\), where \(W\) is the set of points of \(\Gamma\) for which the equation

\[
(7.13) \quad y_1^{s^2+1} + y_2^{s^2+1} + y_3^{s^2+1} = 0
\]

is satisfied. Bose shows that

\[
(7.14) \quad |W| = s^3 + 1;
\]

\[x_1(D) = 1\] and \[x_{s^2+1}(D) = s^2, \ D \in W;\]
\[ x_1(D) = s + 1 \text{ and } x_{s+1}(D) = s^2 - s , \quad D \in \mathcal{W}; \]

otherwise, \( x_{\gamma}(D) = 0. \)

We prove the following theorem by applying Lemma 7.2 and comparing parameters with (2.5).

**THEOREM 7.4.** \( \mathcal{G}(\mathcal{W}) \) is a two-class PBIB design with parameters

\[ (7.15) \quad v = s^6, \]
\[ n_1 = (s^2 - 1)(s^3 + 1), \]
\[ p_{11} = s^2(s^2 + 1) + s^3 - 2, \]
\[ p_{12} = s^2(s^2 - 1), \]
\[ r = s^3 + 1, \]
\[ k = s^2, \]
\[ b = s^4(s^2 + 1), \]
\[ \lambda_1 = 1, \]
\[ \lambda_2 = 0. \]

This design is of negative Latin square type \( \text{NL}_{g}(s^3), \quad g = s^2 - 1. \)

Three other designs \( \mathcal{G}_0(\mathcal{W}), \mathcal{G}_1(\mathcal{W}), \) and \( \mathcal{G}_{s+1}(\mathcal{W}) \) with the same association scheme can be constructed from \( \mathcal{W} \) by the methods of Theorems 7.2 and 7.3. These designs have the same association scheme parameters as the designs \( \mathcal{G}_{\gamma}(Q) \) and \( \mathcal{G}_{\gamma}(Q), \quad t = 3, \) but have different design parameters \( r, k, b, \lambda_1. \)

The following tables give the parameters of the designs constructed in this section which have \( \text{NL}_{g} \) association schemes with \( v \leq 100. \) Additional designs exist, of course, for these association schemes.
### TABLE 7.2

</table>
8. Association schemes with $p^1_{ll} = 0$. We begin with a theorem which holds for any two-class association scheme $G$ with $p^1_{ll} = 0$, then derive stronger results for NL$_g$ schemes with this property.

We define the following sets for a two-class association scheme.

\[(8.1)\quad S_0 = \{\text{an initial object } \alpha\},\]

\[S_1 = \{\text{the } n_1 \text{ first associates of } \alpha\},\]

\[S_2 = \{\text{the } n_2 \text{ second associates of } \alpha\}.\]

Interpreted as sets of rows and columns, these sets define the following partition of $A_1$, the first association matrix of $G$. This is the same partition used in (4.17). Submatrix $B_1$ reduces to a zero matrix because $p^1_{ll} = 0$.

\[(8.2)\quad A_1 = \begin{bmatrix}
0 & 1 & \ldots & 1 & 0 & \ldots & 0 \\
1 & \vdots & & \vdots & C_1 \\
0 & \vdots & C_1^T & & D_1 \\
0 & \vdots & \vdots & & \vdots
\end{bmatrix}.

Theorem 8.1. If $p^1_{ll} = 0$ in a two-class association scheme with parameters $v, n_1, p^1_{jk}$, then

(i) $C_1$ as defined in (8.2) is the incidence matrix of a BIB design $G$ with parameters

$$\hat{v} = n_1, \hat{b} = n_2, \hat{r} = p^1_{12}, \hat{k} = p^2_{11}, \hat{\lambda} = p^2_{11} - 1;$$
(ii) any block of \( \mathcal{C} \) is disjoint from at least \( p_{12}^2 \) other blocks.

Proof. \( C_1 \) is a matrix of 0's and 1's with \( n_1 = \tilde{\kappa} \) rows and \( n_2 = \hat{b} \) columns. The column totals of \( C_1 \) are equal to the row totals of \( C_1^T \), which by Lemma 4.5 are uniformly equal to \( p_{11}^2 = \tilde{\kappa} \). Statement (4.21) of Theorem 4.6, with \( B_1 = 0, B_2 = J - I, p_{12}^1 = n_1 - p_{11}^1 - 1 = n_1 - 1 \), reduces to

\[
C_1 C_1^T = p_{12}^1 I + (p_{11}^2 - 1)(J - I).
\]

By Corollary 4.7.1 this proves (i).

By (4.23), the matrix \( C_1^T C_1 + D_1^2 \) must have elements \( p_{11}^1 = 0 \) in all positions occupied by 1's in \( D_1 \), and by Lemma 4.5 there are exactly \( p_{12}^2 \) such positions in each row. Since \( D_1^2 \) has non-negative elements, any row of \( C_1^T C_1 \) must contain at least \( p_{12}^2 \) zero elements. But the \( i \)-th element of a particular row \( \beta \) of \( C_1^T C_1 \) can be interpreted as the number of objects which the \( i \)-th block of \( \mathcal{C} \) has in common with block \( \beta \), proving (ii).

For the rest of this section, \( \mathcal{C} \) will be taken as an \( NL_g(n) \) scheme with

\[
p_{11}^1 = g^2 + 3g - n = 0.
\]

\( A_1 \) will denote the first association matrix of this scheme. Expressing

\[
n = g^2 + 3g,
\]

\( \mathcal{C} \) has parameters

\[(8.3)\] \( v = n^2 = g^2(g + 3)^2, \)

\[
n_1 = g(g^2 + 3g + 1), \]

\[
n_2 = (g^2 + 2g - 1)(g^2 + 3g + 1), \]
\[ p_{11} = 0, \]
\[ p_{12}^1 = g^3 + 3g^2 + g - 1 = (g+1)(g^2 + 2g + 1), \]
\[ p_{22}^1 = g^4 + 4g^3 + 3g^2 - 2g = g(g + 2)(g^2 + 2g - 1), \]
\[ p_{11}^2 = g^2 + g = g(g + 1), \]
\[ p_{12}^2 = g^3 + 2g^2 = g^2(g + 2), \]
\[ p_{22}^2 = g^4 + 4g^3 + 4g^2 - g - 2 = (g + 1)(g + 2)(g^2 + g - 1), \]
\[ \sigma = g^2 + 2g - 1, \]
\[ \tau = g. \]

Theorem 3.1 shows in this case that \( C_1 \) is the incidence matrix of a BIB design which has parameters

\[(8.4) \quad v = n_1 = g(g^2 + 3g + 1),\]
\[ b = n_2 = (g^2 + 2g - 1)(g^2 + 3g - 1),\]
\[ r = p_{12}^1 = (g + 1)(g^2 + 2g - 1),\]
\[ k = p_{11}^2 = g(g + 1),\]
\[ \lambda = p_{11}^2 - 1 = g^2 + g - 1,\]

and which has the property that

\[(8.5) \quad \text{each block is disjoint from at least } p_{12}^2 = g^2(g+2) \text{ other blocks.}\]

The existence of such a design is thus a necessary condition for the existence of the \( N_L(g^2 + 3g) \) association scheme. The next lemma and two theorems will show that it is sufficient as well and that the design can be used to construct scheme \( \zeta \). The proof of sufficiency must be based on a
design which is not assumed to arise from an association scheme. Let \( \chi \) be a BIB design which has parameters (8.4) and property (8.5) but is otherwise arbitrary. Let \( X_1 \) be the incidence matrix of this design, so that

\[
X_1 X_1^T = \hat{r} I + \hat{\lambda} (J - I) = \frac{1}{p_{12}} I + (p_{11}^2 - 1)(J - I),
\]

and let

\[
X_2 = J - X_1.
\]

Matrix \( C_1 \) may be regarded as a special case of \( X_1 \).

We may regard sets \( S_1 \) and \( S_2 \) respectively as the set of rows and the set of columns of matrix \( X_1 \), or we may regard them as the set of objects and the set of blocks in the corresponding design. The latter interpretation is convenient for the definition of the following sets.

\[
S_{11} = \{ \text{the } p_{11}^2 \text{ objects in an initial block } \gamma \},
\]

\[
S_{12} = \{ \text{the remaining } p_{12}^2 \text{ objects of } S_1 \},
\]

\[
S_{20} = \{ \text{block } \gamma \},
\]

\[
S_{21} = \{ \text{a set of } p_{12}^2 \text{ blocks disjoint from } \gamma \},
\]

\[
S_{22} = \{ \text{the remaining } p_{22}^2 \text{ blocks of } S_2 \}.
\]

Lemma 8.2. Let a BIB design \( \chi \) have parameters (8.4) and property (8.5). Then each block of \( \chi \) is disjoint from exactly \( p_{12}^2 \) blocks and intersects each remaining block in exactly \( g \) objects.
Proof. In the terminology of (6.7), let \( f_1 \) denote the number of objects common to block \( \gamma \) and the \( i \)-th remaining block. Since \( f_1 = 0 \) for all blocks of \( S_{21} \), the well-known formulas due to Hussain [15],

\[
\sum_{i} f_1 = k (r - 1),
\]

\[
\sum_{i} f_1^2 = k \bar{r} (r - 1) + k (k - 1) (\lambda - 1),
\]

remain valid if the summation is restricted to the blocks of \( S_{22} \). Straightforward computation shows that the \( f_1 \)'s for this subset have mean \( g \) and satisfy

\[
\sum (f_1 - g)^2 = 0,
\]

showing that \( \gamma \) intersects each block of \( S_{22} \) in exactly \( g \) objects. Finally, \( \gamma \), which is an arbitrary block, is disjoint from precisely the \( p_{12}^2 \) blocks of \( S_{21} \). This proves the lemma.

This lemma depends on the parameters (6.3) and fails in general for the BIB design described in Theorem 2. It appears therefore that the construction method of this section for \( NLg(g^2 + 3g) \) schemes will not be applicable to other two-class schemes with \( p_{11}^1 = 0 \).

In each row of the symmetric matrix \( X_1 X_1^T \), the element in diagonal position is equal to \( k = p_{11}^2, p_{12}^2 \) elements are equal to 0, and the \( p_{22}^2 \) other elements are equal to \( g \). Thus, we may express

\[
(8.9) \quad X_1^T X_1 = p_{11}^2 I + 0 \cdot Y_1 + gY_2,
\]

where \( Y_1 \) and \( Y_2 \) are matrices of 0's and 1's, each row of \( Y_1 \) contains \( p_{12}^2 \) 1's, each row of \( Y_2 \) contains \( p_{22}^2 \) 1's, and
(8.10) \( I + Y_1 + Y_2 = J, \)

where \( J \) is a \( b \times b \) matrix of 1's. \( Y_1 \) and \( Y_2 \) are symmetric because \( X_1^T X_1 \) is symmetric.

Theorem 8.3. If \( A_1 \), the first association matrix of an \( NL_g (g^2 + 3g) \) scheme with parameters \( v, n_1, p_{jk}^1 \) given by (8.3), then \( C_1^T \) and \( D_1 \) as defined in (8.2) are respectively the incidence matrix and first association matrix of a two-class PBIB design \( C' \) and association scheme \( \gamma \) with the following parameters.

\[ \begin{align*}
\hat{v} &= n_2, \quad \hat{b} = n_1, \quad \hat{\gamma} = p_{11}^2, \quad \hat{k} = p_{12}^1, \quad \hat{\lambda}_1 = 0, \quad \hat{\lambda}_2 = g, \\
\tilde{n}_1 &= p_{12}^2, \\
\tilde{n}_2 &= p_{22}^2, \\
\tilde{p}_{11} &= 0, \\
\tilde{p}_{12} &= g^3 + 2g^2 - 1 = (g+1)(g^2+g-1), \\
\tilde{p}_{22} &= g^4 + 3g^3 + 2g^2 - g - 1 = (g+1)^2(g^2+g-1), \\
\tilde{p}_{11} &= g^2, \\
\tilde{p}_{12} &= g^3 + g^2 = g^2(g+1), \\
\tilde{p}_{22} &= g^4 + 3g^3 + 3g^2 - g - 3.
\end{align*} \]

Proof. The values \( \tilde{v}, \hat{b}, \tilde{\gamma} \) and \( \hat{k} \) follow from Theorem 8.1. From (4.23),

\[ (8.12) \quad C_1^T C_1 + D_1^2 = n_1 I + 0. D_1 + p_{11}^2 D_2. \]

From (8.9), denoting by \( \tilde{Y}_i \), \( i = 1, 2 \), the form taken by \( Y_i \) in the case \( X_1 = C_1 \),

\[ (8.13) \quad C_1^T C_1 = p_{11}^2 I + 0. \tilde{Y}_1 + g \tilde{Y}_2. \]
By subtraction,
\[ D_1^2 = (n_1 - p_{11}^2) I + p_{11}^2 D_2 - g \tilde{Y}_2. \]
\[ \tilde{Y}_2 \text{ and } D_2 \text{ are matrices of } 0's \text{ and } 1's, \text{ each with } 0's \text{ on the main diagonal and each with exactly } p_{22}^2 \text{ 1's in each row. If } \tilde{Y}_2 \neq D_2, \text{ negative elements will occur in off-diagonal positions in the difference } p_{11}^2 D_2 - g \tilde{Y}_2 \text{ and hence in } D_1^2. \text{ But this is impossible, since } D_1 \text{ has non-negative elements. Therefore } \tilde{Y}_2 = D_2, \tilde{Y}_1 = D_1, \text{ and we compute}
\]
\[
(8.14) \quad C_1^T C_1 = p_{11}^2 I + 0.D_1 + g D_2,
\]
\[
(8.15) \quad D_1^2 = p_{12}^2 I + 0.D_1 + g^2 D_2.
\]
Now \( D_1 \) and \( D_2 \) are symmetric matrices of 0's and 1's satisfying \( I + D_1 + D_2 = J \), and (8.15) is sufficient to show by Theorem 4.4 that \( D_1 \) is the first association matrix of a two-class association scheme with parameters \( \tilde{r}_1 = p_{12}^2, \tilde{r}_{11}^1 = 0, \tilde{r}_{11}^2 = g^2 \). (8.14) is then sufficient to show by Corollary 4.7.1 that \( C_1^T \) is the incidence matrix of a PBIB design with this association scheme and with parameters including \( \tilde{X}_1 = 0, \tilde{X}_2 = g \). This implies the rest of (8.11) and the proof is complete.

All of the nontrivial submatrices of \( A_1 \) have now been identified with the BIB design \( \mathcal{C} \) or its dual. This motivates the next theorem in which matrices furnished by the design \( \mathcal{X} \) are used in the definition of an association matrix.

Theorem 8.4. Let \( X_1 \) be the incidence matrix of a BIB design with parameters (8.4) and property (8.5), and define \( X_2, Y_1, Y_2 \) by (8.6), (8.9), (8.10). Let \( A_1^* \) be the matrix
Then $A_{1}^{*}$ is the first association matrix of an NL_{g}(g^2+3g) scheme with parameters (8.3).

Proof. In Theorem 4.6, take $A_{1} = A_{1}^{*}$, $B_{1} = 0$, $C_{1} = X_{1}$, $D_{1} = Y_{1}$. $A_{1}^{*}$ is a matrix of 0's and 1's; the same is true of $A_{2}^{*} = J - I - A_{1}^{*}$, since the diagonal elements of $Y_{1}$ are 0's. $Y_{1}$ is symmetric. From (8.9), $X_{1}^{T}$ has uniform row sums $\tilde{r} = p_{11}^{2}$. We have verified (4.18) to (4.20). In order to prove by Theorem 4.6 that $A_{1}^{*}$ is the specified association matrix it now suffices to verify (4.21) to (4.23), which reduce to

\begin{align}
(8.17) \quad & X_{1}X_{1}^{T} = p_{12}^{1} I + (p_{11}^{2} - 1)(J - I), \\
(8.18) \quad & X_{1}Y_{1} = p_{11}^{2} X_{2}, \\
(8.19) \quad & X_{1}^{T}X_{1} + Y_{1}^{2} = n_{1} I + p_{11}^{2} Y_{2}. 
\end{align}

(8.17) is equivalent to (8.6). The known row and column sums of $X_{1}$ and $Y_{1}$ give the following relations, in which matrices of 1's of various orders are all denoted by the same letter $J$.

\begin{align}
(8.20) \quad & X_{1}J = p_{12}^{1} J, \\
(8.21) \quad & JX_{1} = p_{11}^{2} J, 
\end{align}
\[(8.22) \quad x_1^T J = p_{11}^2 J,\]
\[(8.23) \quad J y_1 = p_{12}^2 J.\]

Solving (8.9) and (8.10) for \( y_1, \)

\[(8.24) \quad y_1 = g I + J - g^{-1} x_1^T x_1.\]

We next multiply on the left by \( x_1 \) and apply (8.20) and (8.6).

\[x_1 y_1 = g x_1 + x_1 J - g^{-1} x_1 x_1^T x_1\]
\[= g x_1 + p_{12}^2 J - g^{-1} \left[ (p_{12}^2 - p_{11}^2 + 1) I + (p_{11}^2 - 1) J \right] x_1.\]

(8.21) is applied and the result is simplified with the aid of (8.3) to give

\[(8.25) \quad x_1 y_1 = p_{11}^2 (J - x_1),\]

proving (8.18). We now multiply (8.24) on the right by \( y_1 \) and apply (8.23) and (8.25).

\[y_1^2 = g y_1 + J y_1 - g^{-1} x_1^T x_1 y_1\]
\[= g y_1 + p_{12}^2 J - g^{-1} p_{11}^2 x_1^T (J - x_1).\]

(8.22) and (8.9) are applied and the result is simplified with the aid of (8.3) and (8.10) to give

\[(8.26) \quad y_1^2 = p_{12}^2 I + g^2 y_2.\]

Adding (8.9) and (8.26) gives (8.19), completing the proof.
We are now assured that if matrix $X_1$ exists, then even though it was not assumed to occur, as $C_1$ does, as a submatrix of an association matrix, it does in fact play exactly this role in $A^*_1$. Moreover, $A^*_1$ is unique for a given $X_1$. The design $\mathcal{D}$ and matrices $X_1, X_2$ will hereafter be denoted by $C, C_1, C_2$. We also drop the distinction between $A_1$ and $A^*_1$.

The following corollary paraphrases Theorem 7.4 in terms of objects and blocks of $C$, without use of the matrices $A_1$ or $C_1$.

Corollary 8.4.1. Let $C$ be a BIB design with parameters $(8,4)$ and property $(8,5)$. Define a two-class association relation $G$ on the set of objects $S_0 \cup S_1 \cup S_2$, where

\[(8.27)\]

\[S_0 = \{\text{an initial object } \alpha\},\]

\[S_1 = \{\text{objects } \beta_i \text{ of } C\},\]

\[S_2 = \{\text{blocks } \gamma_j \text{ of } C\},\]

and sets of first associates are defined as follows.

<table>
<thead>
<tr>
<th>Object</th>
<th>Set of first associates</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\alpha$</td>
<td>$S_1$</td>
</tr>
<tr>
<td>$\beta_i$</td>
<td>$S_0 \cup {\text{blocks of } S_2 \text{ containing } \beta_i}$</td>
</tr>
<tr>
<td>$\gamma_j$</td>
<td>${\text{objects of } S_1 \text{ contained in } \gamma_j} \cup {\text{blocks of } S_2 \text{ disjoint from } \gamma_j}$</td>
</tr>
</tbody>
</table>

Then $G$ is an $NL_g(g^2 + 3g)$ scheme, with parameters $(8,3)$.

The following table lists the important parameters of $C$ and $G$ for a few values of $g$. $D_J$ denotes the number of blocks of $C$ which are disjoint from any given block.
<table>
<thead>
<tr>
<th>Parameters of BIB design C</th>
<th>$\hat{v}$</th>
<th>$\hat{b}$</th>
<th>$\hat{r}$</th>
<th>$\hat{k}$</th>
<th>$\hat{\lambda}$</th>
<th>DJ</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters of NLg scheme G</td>
<td>g</td>
<td>n</td>
<td>$n_1$</td>
<td>$n_2$</td>
<td>$p_{12}^1$</td>
<td>$p_{11}^2$</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>16</td>
<td>5</td>
<td>10</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>2</td>

</tbody>
</table>

Let $A_1$ be partitioned into submatrices whose sets of rows and columns are $S_0, S_{11}, S_{12}, S_{20}, S_{21}, S_{22}$. This is a refinement of the partition (8.2). The submatrix, say $\tilde{O}$, with $S_{11}$ as its row set and $S_{21}$ as its column set falls in $Q_1$, the incidence matrix of BIB design $C$. $\tilde{O}$ is a zero submatrix, since by (8.8) no object of $S_{11}$ is in any block of $S_{21}$. Define notation as follows for other submatrices of $A_1$.

(8.28)

$$
Q_1 = \begin{bmatrix}
1 & \tilde{O} & E_1 \\
\vdots & \vdots & \vdots \\
1 & 0 & F_1 \\
0 & \vdots & G_1 \\
0 & \vdots & \vdots \\
0 & \vdots & \vdots \\
\end{bmatrix}
$$

The submatrix, say $\hat{O}$, with $S_{21}$ as its row and column set falls in $D_1$, the first association matrix of association scheme $\alpha$. Since $S_{21}$ is the set of first associates in $\alpha$ of initial object $\beta$, and $p_{11} = 0$, it follows from Lemma 4.5 that $\tilde{O}$ is a zero submatrix. Define notation as follows for other submatrices of $D_1$. 

$\tilde{O}$.
Let \( A_1 \) be now written as follows. The table below indicates the column sets, and also applies to the row sets.

\[
\begin{bmatrix}
0 & 1 & \cdots & 1 & 0 & \cdots & 0 \\
l & \cdots & 0 & \tilde{0} & H_1 \\
1 & \cdots & 0 & T & K_1 \\
0 & \cdots & H_1 & K_1 \\
0 & \cdots & 0 & \cdots & 0 & \cdots & 0
\end{bmatrix}
\]

\[
A_1 = \begin{bmatrix}
0 & 1 & \cdots & 1 & 1 & \cdots & 1 & 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \\
1 & \cdots & 0 & 0 & 1 & \cdots & 0 & \tilde{0} & E_1 \\
1 & \cdots & 0 & 0 & 1 & \cdots & 0 & F_1 & G_1 \\
0 & \cdots & 0 & H_1 & 0 & \cdots & 0 & H_1 & K_1 \\
0 & \cdots & 0 & H_1 & 0 & \cdots & 0 & H_1 & K_1
\end{bmatrix}
\]

<table>
<thead>
<tr>
<th>Set of columns</th>
<th>( S_0 )</th>
<th>( S_{11} )</th>
<th>( S_{12} )</th>
<th>( S_{20} )</th>
<th>( S_{21} )</th>
<th>( S_{22} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Columns</td>
<td>1</td>
<td>( \frac{n}{1} )</td>
<td>( \frac{n}{1} )</td>
<td>( \frac{n}{1} )</td>
<td>( \frac{n}{1} )</td>
<td>( \frac{n}{1} )</td>
</tr>
</tbody>
</table>

**Theorem 8.5.** If \( A_1 \), the first association matrix of an NL\(_g\)\( (g^2+3g) \) scheme, is partitioned as in (8.30), submatrices \( E_1, F_1, G_1, H_1 \) are incidence matrices of BIB designs, say \( E, F, G, H, \) with parameters as follows.
<table>
<thead>
<tr>
<th>Matrix</th>
<th>$v$</th>
<th>$b$</th>
<th>$r$</th>
<th>$k$</th>
<th>$\lambda$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$E_1$</td>
<td>$g(g+1)$</td>
<td>$(g+1)(g+2)(g^2+g-1)$</td>
<td>$(g+2)(g^2+g-1)$</td>
<td>$g$</td>
<td>$(g-1)(g+2)$</td>
</tr>
<tr>
<td>$F_1$</td>
<td>$g^2(g+2)$</td>
<td>$g^2(g+2)$</td>
<td>$g(g+1)$</td>
<td>$g(g+1)$</td>
<td>$g$</td>
</tr>
<tr>
<td>$G_1$</td>
<td>$g^2(g+2)$</td>
<td>$(g+1)(g+2)(g^2+g-1)$</td>
<td>$(g+1)(g^2+g-1)$</td>
<td>$g^2$</td>
<td>$(g-1)(g+1)$</td>
</tr>
<tr>
<td>$H_1$</td>
<td>$g^2(g+2)$</td>
<td>$(g+1)(g+2)(g^2+g-1)$</td>
<td>$(g+1)(g^2+g-1)$</td>
<td>$g^2$</td>
<td>$(g-1)(g+1)$</td>
</tr>
</tbody>
</table>

Each of designs $\xi, \eta, \zeta$ has the property that each block is disjoint from at least $g^2(g+1)$ other blocks.

Proof. The results for $H_1$ follow from Theorem 8.1, applied to association scheme $\phi$.

The proof for $E_1, F_1, G_1$ will use Corollary 4.7.1. It is easily verified, say from (8.30) and (8.3), that each of these matrices has the size $v \times b$ stated for it in the theorem, and that $F_1^T$ has the same size as $F_1$.

We next show that each of $E_1, G_1, F_1$ has uniform column totals which are equal respectively to $g, g^2, g(g+1)$. This is proved for $E_1$ by applying Lemma 8.2 to design $C$, making use of the block $\gamma$ corresponding to the first column of $C_1$. The result for $G_1$ then follows by subtraction from $g^2+g$, the uniform column total of $C_1$. Let $\eta_0$ be any column of $F_1^T$ and let $\eta$ be the column of $A_1$ which includes $\eta_0$. It is clear from (8.30) that the sum of the 1's of $\eta_0$ is equal to the inner product of columns $\eta$ and $\gamma$, where $\gamma$ is the column in $S_{20}$. But for any $\eta \in S_{12}, \eta$ and $\gamma$ are second associates and have inner product $p_{11}^2 = g(g+1)$, proving that $F_1^T$ has uniform column totals $g(g+1)$.

We now need, in part, the products $C_1^T C_1$ and $C_1^T C_1$, in partitioned form, computed in two ways. By multiplication of the partitioned matrix $C_1$,
(8.31) \[ C_1^T C_1 = \begin{bmatrix} J + E_1 E_1^T + F_1^T F_1 \end{bmatrix} \]

\[ \frac{F_1^T F_1}{E_1^T E_1 + G_1^T G_1} \]

(8.32) \[ C_1^T C_1 = \begin{bmatrix} F_1^T F_1 \end{bmatrix} \]

\[ \frac{E_1^T E_1 + G_1^T G_1}{E_1^T L + G_1^T G_1} \]

From (8.6) and (8.14),

(8.33) \[ C_1^T C_1 = \begin{bmatrix} p_{12}^1 I + (p_{11}^2 - 1)(J-I) \end{bmatrix} \]

\[ \frac{p_{12}^1 I + (p_{11}^2 - 1)(J-I)}{p_{12}^1 I + (p_{11}^2 - 1)(J-I)} \]

(8.34) \[ C_1^T C_1 = \begin{bmatrix} g(g+1)I + g(J-I) \end{bmatrix} \]

\[ \frac{g(g+1)I + 0.K_1 + gK_2}{g(g+1)I + 0.K_1 + gK_2} \]

where \( K_2 = J - I - K_1 \) is a submatrix of \( D_2 \).

If (8.31) and (8.33) are solved for \( E_1 E_1^T \), Corollary 4.7.1 now shows that \( \mathcal{G} \) is a BIB design with the parameters stated in the theorem.

If (8.32) and (8.34) are solved for \( F_1 F_1^T \), Corollary 4.7.1 now shows that \( F_1 \) is the incidence matrix of a BIB design with \( v = b = g^2(g+2) \), \( r = k = g(g+1) \), \( \lambda = g \). Since this is a symmetric design, the dual design \( \mathcal{G} \) is balanced and has the same parameters.

The product \( F_1 F_1^T \) is now known, making it possible to solve (8.31) and (8.33) for \( G_1 G_1^T \), and one more application of Corollary 4.7.1 shows that \( \mathcal{G} \) is a BIB design with the parameters stated in the theorem.

Submatrix \( K_1 \) in (8.29) has the same relation to \( D_1 \) as submatrix \( D_1 \) in (4.17) has to \( A_1 \), and Lemma 4.5 shows that \( K_1 \) has uniform row totals.
\[ \tilde{p}_{12} = s^2 (g+1). \] There must therefore be at least this number of zero elements in each row of the matrix \( g(g+1) I + 0.K_1 + gK_1^2 \), and comparison of (8.32) with (8.34) shows that the same is true of \( E_{11}^T + G_{11}^T \). This means that any column of matrix \( [\frac{1}{\tilde{p}_{11}}] \) has inner product zero with at least \( g^2 (g+1) \) other columns. In particular, this must hold for the inner product of any column of \( E_1 \) with other columns of \( E_1 \), and similarly for \( G_1 \). This proves that designs \( \mathcal{C} \) and \( \mathcal{A} \) have the property stated in the last sentence of the theorem. The proof is now complete.

Design \( \mathcal{C} \) is trivial in the case \( g = 1 \), giving a fourth method of construction of the \( \text{NL}_1(4) \) scheme. This construction gives an easy proof of the uniqueness of the scheme.

Design \( \mathcal{C} \) is far from trivial for \( g > 2 \), as suggested by the rapidly growing parameters in Table 8.1. Theorems 8.3 and 8.5 give useful information on the structure of the design but have not yet led to proofs of existence or of nonexistence in any of the cases \( g > 3 \). In the case \( g = 2 \) just enough of the structure of \( \mathcal{C} \) is determined that an empirical study is feasible. The author conjectured that the design did not exist in this case, undertook an empirical search in hopes of proving its nonexistence, and in the course of the search inadvertently constructed it.

Design \( \mathcal{C} \) in the case \( g = 2 \) has parameters

\[
(8.35) \quad v = 22, \ b = 77, \ r = 21, \ k = 6, \ \lambda = 5.
\]

Denoting objects by 1, 2, \ldots, 22, a solution of this design is given by the blocks in the following table.

</table>
It is possible to verify by inspection that the foregoing design has property (8.5), that each block is disjoint from 16 other blocks.

Theorem 8.6. The NL$_2$$(10)$ association scheme exists.

Proof. Apply Corollary 8.4.1 to the foregoing BIB design.

The table of first associates requires 100 rows and 22 columns and will be omitted to save space.

By listing the 77 blocks of our BIB design we have been able to prove its existence without describing the empirical construction. This method of proof is reminiscent of Bhaskara whose 1150 A.D. treatise on mathematics presented a sketch of a particularly lucid construction for the Pythagorean theorem, accompanied by the brief written proof, "Behold!"

The situation is different when a claim of nonexistence or uniqueness is based on empirical search. A valid proof must show that the search was exhaustive, and this may involve a description which in written form is more tedious than the search itself. In the next theorem we have attempted to steer between tedium and nonproof by giving enough details that the interested or suspicious reader can fill in the rest.

Theorem 8.7. The NL$_2$$(10)$ association scheme is unique up to permutation of objects.

Proof. Let $\gamma$ be an NL$_5$$(n)$ association scheme, $n = 2g^2 + 3g$, with association matrix $A_1$. An initial object $\alpha$ may be chosen in $n^2$ different ways. For a given $\alpha$, (8.1) determines sets $S_1$ and $S_2$, and (8.2) determines submatrix $C_1$ up to permutation of rows and independent permutation of columns. Theorem 8.1 shows that $C_1$ is the incidence matrix of a BIB design $\gamma$ with parameters (8.4) and property (8.5); for a particular $\alpha$, $\gamma$ is determined up to permutation of objects and permutation of blocks.
Theorem 8.4 shows that any such matrix $C_1$ can be obtained by the same construction from some NL$(g^2, g)$ association scheme $G$, and that a particular $C_1$ determines $A_1$ and $G$ uniquely. Two designs $C$ which differ only in permutation of objects and of blocks lead to schemes $G$ which differ only by a permutation of the objects of $S_1$ and a permutation of the objects of $S_2$. Then association schemes $G$ which are inequivalent under permutation of objects must surely lead to designs $C$ which are inequivalent under permutation of objects and blocks. The number of inequivalent schemes $G$ is less than or equal to the number of inequivalent designs $C$, and $G$ is unique if $C$ is unique.

The theorem will be proved by showing that $C$ is unique in the case $g = 2$. It has parameters $(8, 35)$,

$$
\nu = 22, \ b = 77, \ r = 21, \ k = 6, \ \lambda = 5,
$$

and the property that any block is disjoint from 16 other blocks. By Lemma 8.2, each of the remaining 60 blocks intersects the given block in exactly two objects.

Without loss of generality we may assume that the initial block $\gamma$ is

$$1 2 3 4 5 6,$$

$$S_{11} = \{1, 2, 3, 4, 5, 6\},$$

$$S_{12} = \{7, 8, \ldots, 22\}.$$

$S_{21}$ is a set of $P_{12}^2 = 16$ blocks, each containing six objects of $S_{12}$, comprising the blocks of a symmetric BIB design $G$ with $\lambda = 2$. Each of the $P_{22}^2 = 60$ blocks of $S_{22}$ is the union of a block of design $G$, containing two objects of $S_{11}$, and a block of design $G$, containing four objects of $S_{12}$. Design $G$ is uniquely determined by its parameters.
\[ v = 6, \ b = 60, \ r = 20, \ k = 2, \ \lambda = 4 \]

to have as its blocks the 15 pairs \((i, j) = (j, i)\) of distinct objects of \(S_{11}\), each pair repeated four times.

\(C(i, j)\) will denote the set of four blocks of \(C\) which contain a pair \(i, j\) of distinct objects of \(S_{11}\), and \(q(i, j)\) will denote the set of four blocks of \(Q\) which are contained in the blocks of \(C(i, j)\). Any two blocks of \(C\) which are not disjoint must intersect in exactly two objects, showing that

\[(8.36)\] the four blocks of \(q(i, j)\) are pairwise disjoint.

Thus for each \((i, j)\), the blocks of \(q(i, j)\) contain all 16 of the objects of \(S_{12}\). Also,

\[(8.37)\] a block of \(q(i, j)\) and \(q(i, k)\), \(j \neq k\), must have exactly one object in common.

Thus the four objects of any block of \(q(i, j)\) are distributed one each over the four blocks of \(q'(i, k)\). Also if \(i, j, k, l\) are pairwise distinct, the objects of any block of \(q(i, j)\) occur two each in two blocks of \(q(k, l)\).

Using the remarks of the preceding paragraph it is easy to choose notation for the objects of \(S_{12}\) and permute blocks within sets \(C(i, j)\) so that \(C(1, 2)\), \(C(3, 4)\), \(C(3, 5)\) and \(C(4, 5)\) are determined to the following extent
We must now decide whether to assign the pair 13, 14 in $C(3, 4)$ to positions $x, y$ or to some other block. In the latter case we may assume $x, y = 15, 16$, which requires $z = 15$ or 16; then object 15 cannot occur anywhere in $C(4, 5)$ without violating (8.37). This contradiction shows that $x, y = 13, 14$.

If one block of $G(3, 4)$ is 7 8 11 12, then another block must be 9 10 13 14. This reasoning was used to assign the objects of two blocks of $G(1, 2)$ to the blocks of $G(3, 4)$ but it applies more generally to show that

\[(8.38) \text{ if } i, j, k, l \text{ are pairwise distinct, the objects of any block of } G(i, j) \text{ occur two each in two blocks of } G(k, l), \text{ and the remaining four objects in these two blocks occur together in another block of } G(i, j).\]

Choice of notation will now give $C(3, 4)$ and $C(3, 5)$ the form listed in Table 8.2. After various applications of (8.36) to (8.38), $C(4, 6)$ and $C(5, 6)$ are determined uniquely and the other $C(i, j)$ are determined in part.
$C(1, 3)$ and $C(2, 3)$ have the form

\[
\begin{array}{cccc}
1 & 3 & 7 & x \ - \\
1 & 3 & 8 & - \\
1 & 3 & 9 & - \\
1 & 3 & 10 & - \\
\end{array}
\quad
\begin{array}{cccc}
2 & 3 & 7 & y \ - \\
2 & 3 & 8 & - \\
2 & 3 & 9 & - \\
2 & 3 & 10 & - \\
\end{array}
\]

where $x$ and $y$ are equal in some order to $13$ and $14$. Objects $1$ and $2$ have played symmetrical roles up to this point and may be exchanged if necessary so that $x = 13$, $y = 14$.

$C(4, 5)$ reduces to one of these two cases.

Case I $\begin{array}{cccc} 4 & 5 & 7 & 10 & 19 & 22 \\ 4 & 5 & 8 & 9 & 20 & 21 \\ 4 & 5 & 11 & 14 & - & - \\ 4 & 5 & 12 & 13 & - & - \end{array}$

Case II $\begin{array}{cccc} 4 & 5 & 7 & 10 & 20 & 21 \\ 4 & 5 & 8 & 9 & 19 & 22 \\ 4 & 5 & 11 & 14 & - & - \\ 4 & 5 & 12 & 13 & - & - \end{array}$

Once either of these cases is assumed, the remaining sets of blocks $C(i, j)$ are determined uniquely by arguments based on (8.36) to (8.38). This may first be established for the sixteen blocks of $C(4, 5)$, $C(3, 6)$, $C(1, 3)$ and $C(1, 4)$ by comparing them to each other and to blocks that have already been determined. The remaining $C(i, j)$ are easily determined, completing the 60 blocks of $S_{22}$.

Case I leads to the blocks listed in Table 8.2. The 60 blocks of $S_{22}$ in Case II are, apart from order, the blocks obtained from those of Case I by a permutation of objects which in cycle form may be expressed

\[(1 2) \quad (11 12) \quad (13 14) \quad (19 20) \quad (21 22).\]

Therefore Case I and Case II are equivalent under permutation of objects and blocks. Case I will be assumed.
It remains to show that the 16 blocks of $S_{21}$ are uniquely determined by the 61 blocks already fixed. The argument, which will be illustrated for one block, repeatedly uses the fact that two blocks of $C$ intersect either in no objects or in two objects. Since these 16 blocks comprise a BIB design with objects 7, 8, ..., 22, and $\lambda = 2$, we may assume that two blocks have the form

(i) $7 \ 8 \ x \ - \ -$
(ii) $7 \ 8 \ - \ - \ -$

The remaining objects in (i) and (ii) must be distinct.

Because of blocks

\[
\begin{align*}
1 & 2 & 7 & 8 & 9 & 10 , \\
3 & 4 & 7 & 8 & 11 & 12 , \\
5 & 6 & 7 & 8 & 13 & 14 ,
\end{align*}
\]

(i) and (ii) cannot contain any of objects 9, 10, 11, 12, 13, 14 and must therefore contain all of objects 15, 16, ..., 22. Let $x = 15$. Then (i) contains the pair 7, 15 and because of blocks

\[
\begin{align*}
3 & 5 & 7 & 9 & 15 & 17 , \\
1 & 6 & 7 & 11 & 15 & 19 , \\
2 & 4 & 7 & 13 & 15 & 21 ,
\end{align*}
\]

(i) cannot contain any of objects 17, 19, 21 and we have

(i) $7 \ 8 \ 15 \ - \ - \ -$
(ii) $7 \ 8 \ 17 \ 19 \ 21 \ -$

Block (ii) contains the pair 7, 19 and because of block

\[
\begin{align*}
4 & 5 & 7 & 10 & 19 & 22
\end{align*}
\]
cannot contain object 22; it contains the pair 17, 19 and because of block

\[ 5 \ 6 \ 17 \ 18 \ 19 \ 20 \]

cannot contain object 18 or 20. We now have

\[(1) \ 7 \ 8 \ 15 \ 18 \ 20 \ 22 \]
\[(ii) \ 7 \ 8 \ 17 \ 19 \ 21 \ - \ . \]

The remaining blocks of \( S_{21} \) may be completed by similar arguments, or by
easier arguments toward the end.

This completes the proof of Theorem 8.7.

We are finished with the contributions of this section to the theory
of negative Latin square association schemes, but we shall mention some by-
products.

Association scheme \( \beta \) in the case \( g = 2 \) is another scheme outside the
Bose-Shimomoto classification and appears to be new. It has parameters

\[(8.39) \ v = 77, \]
\[n_1 = 16, \quad P_1 = \begin{bmatrix} 0 & 15 \\ 15 & 45 \end{bmatrix}, \quad P_2 = \begin{bmatrix} 4 & 12 \\ 12 & 47 \end{bmatrix}. \]
\[n_2 = 60, \]

It is readily constructed by identifying the 77 objects with the blocks of
the BIB design \( \zeta \), and taking two objects as first associates if and only
if the corresponding blocks are disjoint.

We have already noted that the matrix \( A_1 \) has many submatrices of the
form of \( C_1, C_1^T, D_1 \), as the partition (8.2) can be carried out for \( v = n^2 \)
different choices of the initial object \( \alpha \). Submatrices of the form dis-
cussed in Theorem 8.5 are even more numerous, as the refinement of (8.2) to
the partition (8.30) can be carried out for \( n_2 = (g^2 + 2g - 1)(g^2 + 3g + 1) \) different choices of object \( \gamma \). The number of partitions is thus equal to the number \( v_n \) of ordered pairs \( \alpha, \gamma \) of second associates. Each submatrix \( E_1, F_1, F_1^T, G_1, H_1 \) is counted twice in this total, since the ordered pairs \( \alpha, \gamma \) and \( \gamma, \alpha \) lead to partitioned matrices which differ only by an interchange of \( F_1 \) and \( F_1^T \), an interchange of \( G_1 \) and \( H_1 \), and an interchange of \( G_1^T \) and \( H_1^T \). In the case \( g = 2 \), one detail of this is that \( A_1 \) contains 3850 pairs of 16 x 16 submatrices \( F_1 \) and \( F_1^T \) for a total of 7700 incidence matrices of the symmetric design with \( r = 6, \lambda = 2 \). These are all equivalent under permutation of rows and columns. We remark that Hussain [14] has shown that there are just three solutions of this design which are inequivalent, and that the type arising here is his type I.

In the case \( g = 2 \), the 15 sets \( \gamma(i, j) = \gamma(j, i) \), \( 1 \leq i < j \leq 6 \), have a curious interpretation. Each set is an arrangement of the 16 objects 7, 8, ..., 22 into four blocks of four objects. We assign four letters, say A, B, C, D, one each to the four blocks of each \( \gamma(i, j) \). We then arrange the 16 objects in a 4 x 4 array, say

\[
\begin{array}{cccc}
7 & 8 & 9 & 10 \\
11 & 12 & 13 & 14 \\
15 & 16 & 17 & 18 \\
19 & 20 & 21 & 22 \\
\end{array}
\]

and use \( M \) with each \( \gamma(i, j) \) to define a 4 x 4 array \( M(i, j) \) of the letters A, B, C, D by the rule: for each object \( \theta \in \{7, 8, ..., 22\} \) assign the same letter to the position of \( M \) containing \( \theta \) as has been assigned to the block of \( \gamma(i, j) \) containing \( \theta \).

Then each letter occurs in four positions in \( M(i, j) \) and it follows from (8.37) that these positions are occupied by four distinct letters in
M(i, k), j ≠ k. This means that M(i, j) and M(i, k) are orthogonal 4 x 4 squares, and for fixed i, the five distinct squares M(i, j), 1 ≤ j ≤ 6, j ≠ i, are a complete orthogonal set of 4 x 4 squares. The simplest assignment of letters A, B, C, D to the blocks of the (i, j) in our solution of the design 2 leads to the squares M(i, j) displayed in the following table.

<table>

</table>

Each square M(i, j) is also listed as M(j, i) in this table. With this duplication, each complete set of five pairwise orthogonal squares is simply the set of squares in one of the six rows. It will be noted that
the only Latin squares are $M(1, 3)$, $M(1, 4)$, $M(1, 5)$ and $M(2, 6)$, the first three forming a complete set of three pairwise orthogonal Latin squares. For a different assignment of objects 7, 8, ..., 22 to array $M$, the $M(i, j)$ will have the same orthogonality properties but need not include any Latin squares.

9. Parameters of designs. The emphasis in most of this paper is on PBIB association schemes rather than actual designs. This section, however, presents and briefly discusses tables of arithmetically possible sets of parameters for designs based on NL$_g(n)$ association schemes. Under "Remarks", the tables include information which has come to the author's attention on existence and non-existence of these designs, with references to published literature or to some results of this section. A more systematic study of detailed properties, construction methods, and nonexistence proofs for NL$_g$ designs will be deferred to a later time. The present discussion and tables are a preliminary report and are intended to facilitate such a study, not take its place. In particular, the author has not made a recent search of the literature on particular designs and may have omitted some published results from the tables or duplicated them in the following paragraphs.

Given a set of parameters $v$, $n_i$, $p_{jk}$, $\sigma$, $\tau$, $\alpha_i$ for a two-class scheme, we define a set of design parameters $b$, $r$, $k$, $\lambda_i$, $\theta_i$ to be arithmetically possible if the following well-known necessary conditions are satisfied.

$$rv = bk,$$

$$n_1^{\lambda_1} + n_2^{\lambda_2} = r(k-1).$$
\[ \theta_i \geq 0; \ i = 1 \text{ and } 2; \]

if \( \theta_i > 0, \ i = 1 \text{ and } 2 \), then \( b \geq v \);

if \( \theta_i = 0, \ i = 1 \text{ or } 2 \), then \( b \geq v - \alpha_i \).

The special case \( \lambda_1 = \lambda_2 \) reduces to a balanced design and will be omitted.

These conditions apply to all two-class designs but our tables are restricted to the negative Latin square family. We assume \( n_1 < n_2 \) (in particular omitting NLg parameters with \( n_1 = n_2 \), which are already available in tables of Latin square parameters.) The tables include NLg parameters for

- all designs with \( r \leq 10, \ k \leq 10 \), all \( v \),
- all designs with \( r \leq 15, \ k \leq 15 \), \( v \leq 100 \),
- and selected designs with \( r > 15 \) or \( k > 15 \), \( v \leq 100 \).

This range was determined by the desire to include a representative sample of designs while keeping the tables at a reasonable length. It will be observed that only a small proportion of the parameter sets are in the range \( r \leq 10, \ k \leq 10 \) which has traditionally been called practical.

Given an association scheme with parameters \( v, n_1, \ p_{jk} \), the following are some simple methods by which designs can be generated from the association scheme itself.

In this and the two following paragraphs, \( i \) and \( j \) represent 1 and 2 in some order. A design with parameters

\[(9,2) \quad v, \ b = vn_1/2, \ r = n_1, \ k = 2, \ \lambda_i = 1, \ \lambda_j = 0 \]

can be constructed by taking as blocks all pairs of \( i \)-th associates.
A design with parameters

\[(9.3)\quad v = b, \quad r = k = n_i, \quad \lambda_1 = p_{ii}^i, \quad \lambda_j = p_{ii}^j\]

can be constructed by taking block \(\theta\) as the set \{i-th associates of \(\theta\)\}.

A design with parameters

\[(9.4)\quad v = b, \quad r = k = n_i+1, \quad \lambda_1 = p_{ii}^i + 2, \quad \lambda_j = p_{ii}^j\]

can be constructed by taking block \(\theta\) as the set \[\{\theta\} \cup \{i-th associates of \theta\}\].

In the Remarks column of the following tables, the notation \(R(a, b, \ldots, c)\) for a design indicates that it can be obtained by replication from the designs for the same association scheme with serial numbers \(a, b, \ldots, c\). Its blocks may be listed by merging the lists of blocks of those designs.

Each block in a particular design, regarded as a set of \(k\) objects, uniquely determines the complementary set of \(v-k\) objects. The complements of the \(b\) blocks of a design \(\mathcal{A}\) comprise a second design, the complement of \(\mathcal{A}\). If \(\mathcal{A}\) has incidence matrix \(N\), its complement has incidence matrix \(J-N\) and properties which follow readily from (4.7) if \(\mathcal{A}\) is partially balanced. If a two-class design has parameters \(v, b, r, k, \lambda_1\), the complement has the same association scheme and parameters

\[v, b, r' = b-r, \quad k' = v-k, \quad \lambda_1' = b-2r + \lambda_1\].

Designs (9.3) and (9.4) for opposite choices of \(i\) are complements. A design exists if and only if its complement exists, and a few designs in our tables are disposed of by first proving the existence or non-existence of the complement.
If \( \lambda_j = 0 \) in a 2-class design, each block must be a set of objects which are pairwise \( i \)-th associates. In particular, any two objects of the block must have the remaining \( k-2 \) objects among their \( p_{ii}^1 \) common \( i \)-th associates. This gives us a known [3] necessary condition for a 2-class design, where \( i \) and \( j \) represent 1 and 2 in some order.

\[(9.5) \quad \text{If } \lambda_j = 0, \text{ then } k \leq p_{ii}^1 + 2.\]

A number of designs for which constructions by various methods are known to the author are listed in the tables with the remark, "Constructed, to appear." The details, which are beyond the scope of the present section, will be presented in a later paper.
TABLE 9.1

10. Generalized \( L_g \) and \( NL_g \) designs with \( m \) associate classes. The Latin square family of two-class association schemes and designs can be generalized in a natural way to a larger number of associate classes. The three-class case has been discussed [22] by Singh and Shukla, who were aware of the full generalization. In this section we describe the family of \( m \)-class Latin square association schemes, then define an \( m \)-class negative Latin square scheme.

If there exists a complete set of \( n-1 \) pairwise orthogonal Latin squares of order \( n \), we may obtain a set of \( n + 1 \) pairwise orthogonal squares (not all Latin) by adjoining a square in which the \( i \)-th letter occupies all positions in the \( i \)-th row and a square in which the \( i \)-th letter occupies all positions in the \( i \)-th column.

To define an \( m \)-class association scheme, \( m \leq n+1 \), we arrange the \( n+1 \) orthogonal squares into \( m \) disjoint subsets, where, denoting by \( g_1 \) the number of squares in the \( i \)-th set,

\[
(10.1) \quad g_1 + \ldots + g_m = n+1.
\]

We arrange the \( n^2 \) objects in an \( n \times n \) array and take two objects as \( i \)-th associates if and only if their positions in the array are occupied by the same letter in an orthogonal square of the \( i \)-th subset. It can be shown that this association relation is a partially balanced \( m \)-class scheme with the following parameters.

\[
(10.2) \quad v = n^2,
\]

\[
\pi_i = g_1(n-1),
\]

\[
\rho_{11} = (g_1-1)(g_1-2) + n-2,
\]
\[ p^i_{ij} = p^i_{ji} = g_j(g_i - 1), \]
\[ p^j_{jj} = g_j(g_j - 1), \]
\[ p^i_{jk} = g_j g_k, \]

where \( i, j, k \) are distinct, \( 1 \leq i, j, k \leq m \).

The above definition is more restrictive than necessary. Denoting

\[ g = g_1 + g_2 + \ldots + g_{m-1} = n + 1 - g_m, \]

we may still construct the \( m \)-class Latin square scheme if a set of \( g \) pair-wise orthogonal squares exists (equivalently, \( g-2 \) such Latin squares).

Associate classes \( 1, 2, \ldots, m-1 \) are defined as before and objects are
taken as \( m \)-th associates if they are not associates of any other class.

Expressions (10.2) apply. It may be conjectured that association schemes
with these parameters exist in still more cases, though it may be preferable
to treat them as a generalized pseudo-Latin square family in any cases where
the orthogonal squares are not actually used.

It is now completely straightforward to define a generalized negative
Latin square family of association schemes by using negative integers \( n, \)
\( g_1, \ldots, g_m \) in expressions (10.1) and (10.2). In terms of positive parameters
\( n^*, g_1^* \), we take \( n = -n^* \), \( g_1 = -g_1^* \), and substitute in (10.1) and (10.2).

Dropping the stars, we have

\[ g_1 + \ldots + g_m = n - 1, \]  
\[ v = n^2, \]  
\[ n_i = g_1(n+1), \]
\[ p_{11} = (s_{1}+1)(s_{1}+2) - n - 2, \]
\[ p_{1j} = p_{j1} = s_{j}(s_{1}+1), \]
\[ p_{jj} = s_{j}(s_{j}+1), \]
\[ p_{jk} = s_{j}s_{k}, \]

1, j, k distinct, 1 < i, j, k ≤ m.

These parameters are integers satisfying conditions (1.4) and (1.5) and all except possibly \( p_{11} \) are non-negative. The requirement

\[ p_{11} ≥ 0 \]

places a lower bound on \( s_{i} \) for a given \( n, i = 1, \ldots, m \), and (10.3) then places an upper bound on the number \( m \) of associate classes for a given \( n \).

11. Acknowledgements. Portions of this work appeared in 1956 in the author's Ph.D. thesis at Michigan State University [16]. Section 9 includes portions of unpublished tables which were compiled by the author in 1961 in an investigation for which computer facilities were provided by Purdue University.
