A CLASS OF TRI-WEIGHT CYCLIC CODES

1. INTRODUCTION

Let \( \ell, k \) be positive integers such that \( \ell < k \) and \( (2^\ell + 1, 2^k - 1) = 1 \). Let \( f_0(x) \) be a primitive polynomial of degree \( k \) over \( \text{GF}(2) \), and let \( f_\ell(x) \) be the minimum polynomial of \( \alpha^{2^\ell + 1} \), where \( \alpha \) is a root of \( f_0(x) \). Then the cyclic code \( A \) with recursion polynomial \( f_0(x)f_\ell(x) \) is a \( (2^k - 1, 2k) \) code representing the direct sum of the maximal-length shift register codes with recursion polynomials \( f_0(x), f_\ell(x) \), respectively.

In the case \( k \) odd and \( (\ell, k) = 1 \), Gold [5] and Solomon [11] have shown that the code \( A \) has three non-zero weights. They give the weight distribution and an algebraic characterization of the code words of each weight. Gold [4] obtained a similar result for \( k \equiv 2 \pmod{4} \) and \( \ell = (k + 2)/2 \). We generalize these results to arbitrary \( k \) and \( \ell \) subject to the conditions \( \ell < k, (2^\ell + 1, 2^k - 1) = 1 \). Theorem 1 below shows that \( A \) has three non-zero weights and gives the weight distribution, and Theorem 2 gives an algebraic characterization of the code words of each weight.

Remark. After completing this work, the author learned that the weight distribution (Theorem 1) had been obtained earlier by Kasami [6, 7]. Kasami's proof is purely algebraic and is based on the fact (which he proves) that \( A \) is a subcode of a second-order modified Reed-Muller code of length \( 2^k - 1 \). Our proof involves geometric as well as algebraic methods, and is sufficiently dissimilar to Kasami's to merit its inclusion here. To the author's knowledge, Theorem 2 is new.

2. STATEMENT OF PRINCIPAL RESULTS

Throughout we shall assume \( k \) a fixed positive integer and \( \ell \) an integer such that \( 1 \leq \ell \leq k-1 \). This latter restriction is merely a convenience, since

This research was partially sponsored by the Air Force Office of Scientific Research, United States Air Force, under Grant No. AF-AFOSR-68-1415; the National Science Foundation, under Grant No. GP-8624; and the National Aeronautics and Space Administration - American Society of Electrical Engineers Summer Faculty Fellowship Program.
\[ 2^m + 1 \equiv 2^\ell + 1 \pmod{2^k - 1} \quad \text{if} \quad m \equiv \ell \pmod{k}. \] The case \( \ell = 0 \) is omitted since we require \( f_0(x) \) and \( f_\ell(x) \) to be distinct. We begin by characterizing the set

\[ L(k) = \{ \ell : 1 \leq \ell \leq k-1, \ (2^\ell + 1, \ 2^k - 1) = 1 \} \]

of integers \( \ell \) for which \( f_\ell(x) \) is primitive of degree \( k \) and distinct from \( f_0(x) \).

For any integer \( t \), define \( m(t) \) as the exponent of two in the prime power factorization of \( t \).

**Lemma 1**: \( L(k) = \{ \ell : 1 \leq \ell \leq k-1, \ m(\ell) \geq m(k) \} \).

**Proof**: It is easily verified that if \( a, b, c \) are integers, and \((a, b) = 1\), then \((a, c) = 1\) if and only if \((ab, c) = (b, c)\). Setting \( a = 2^\ell + 1, b = 2^\ell - 1, c = 2^k - 1, \) we have \((2^\ell + 1, 2^k - 1) = 1\) if and only if \((2^{2\ell} - 1, 2^k - 1) = (2^{\ell} - 1, 2^k - 1)\). But \((2^{r} - 1, 2^s - 1) = 2^{(r,s)} - 1\).

Hence \((2^\ell + 1, 2^k - 1) = 1\) if and only if \((2^\ell, k) = (\ell, k)\), i.e., if and only if \( m(\ell) \geq m(k) \).

**Corollary 1**: \( L(k) = \emptyset \) if and only if \( k = 2^m \) for some \( m \geq 0 \).

**Corollary 2**: If \( \ell \in L(k), \ (\ell, k) \equiv k \pmod{2} \) and \( k/(\ell, k) \equiv 1 \pmod{2} \).

**Proof**: Write \( k = 2^m s \), where \( m = m(k) \), and \( \ell = 2^m t \). Then

\[ k + (\ell, k) = 2^m(s + (s, t)), \]

\[ k/(\ell, k) = s/(s, t), \]

and the right-hand expressions are even and odd, respectively, since \( s \) is odd.
THEOREM 1: Suppose \( k \neq 2^m \) for any \( m \geq 0 \), and let \( \ell \in L(k) \). Then the cyclic code \( A \) with recursion polynomial \( f_0(x)f_\ell(x) \) is a \( (2^k - 1, 2k) \) code with three non-zero weights. The weight distribution of \( A \) is given below:

<table>
<thead>
<tr>
<th>Weight</th>
<th>Number of Code Words</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 2^{k-1} )</td>
<td>( (2^k - 1)(2^k - 2^{k-(\ell,k)} - 1) )</td>
</tr>
<tr>
<td>( 2^{k-1} - 2^{(k+(\ell,k)-2)/2} )</td>
<td>( (2^k - 1)(2^{k-(\ell,k)-1} + 2^{(k-(\ell,k)-2)/2}) )</td>
</tr>
<tr>
<td>( 2^{k-1} + 2^{(k+(\ell,k)-2)/2} )</td>
<td>( (2^k - 1)(2^{k-(\ell,k)-1} - 2^{(k-(\ell,k)-2)/2}) )</td>
</tr>
</tbody>
</table>

The proof of Theorem 1, and Theorem 2 below, will be given in Section 5.

Before stating Theorem 2, we require some preliminary remarks on the algebraic characterization of the code words of \( A \), following Solomon [11] and Gold [5].

Let \( a = (a_0, a_1, \ldots, a_{2^k-2}) \) be a code word of \( A \). Then \( a \) is characterized by its Mattson-Solomon polynomial \([8]\)

\[
g_a(x) = \text{Tr} cx + \text{Tr} dx^{2^\ell+1},
\]

where \( c, d \in GF(2^k) \), and \( \text{Tr} x = \sum_{i=0}^{k-1} x^{2^i} \) is the trace of \( GF(2^k)/GF(2) \).

The polynomial \( g_a(x) \) satisfies \( g_a(a^i) = a_i \), where \( a \) is a root of \( f_0(x) \).

Thus the mapping

\[
\psi: a \to (c, d)
\]

is a one-one linear mapping of the code \( A \) onto \( GF(2^k) \times GF(2^k) \). We define \( w(c, d) \) as the weight of the code word \( a = \psi^{-1}(c, d) \).

If \( a \in A \), \( \psi(a) = (c, d) \), a cyclic shift \( T_s \) to the right of length \( s \) maps \( a \to T_s(a) \) and \( (c, d) \to (a^sc, a^s(2^\ell+1)d) \). If \( c \neq 0, d = 0 \), then clearly \( a \in A_0 \), so \( w(c, 0) = 2^{k-1} \). Similarly, if \( c = 0, d \neq 0 \), then \( a \in A_\ell \), \( w(0, d) = 2^{k-1} \). If \( c \neq 0, d \neq 0 \), we can choose \( s \) above so that
\( \delta_s = \frac{1}{2^{\ell+1}} \) since \( 2^{\ell} + 1 \) is prime to \( 2^k - 1 \). Since \( T_s \) is obviously weight-preserving,

\[
   w(c, d) = w(cd, 1).
\]

Thus we can restrict attention to code words \( a \) such that \( \psi(a) = (c, 1) \), where \( c \neq 0 \).

Let \( \text{Tr}_{k/\ell}(k) = \sum_{i=0}^{t-1} x^{2^{i}(\ell,k)} \) denote the trace of \( \text{GF}(2^k)/\text{GF}(2^{\ell,k}) \), where \( t = k/\ell, k \). We then have

**THEOREM 2**: Let \( c \in \text{GF}(2^k), c \neq 0 \). Then

(i) if \( \text{Tr}_{k/\ell}(k) c \neq 1 \),

\[
   w(c, 1) = 2^{k-1}
\]

(ii) if \( \text{Tr}_{k/\ell}(k) c = 1 \),

\[
   w(c, 1) = \begin{cases} 
   w(1, 1) & \text{if } \text{Tr}(\beta + \beta 2^{\ell+1}) = 0, \\
   2^{k} - w(1, 1) & \text{if } \text{Tr}(\beta + \beta 2^{\ell+1}) = 1,
\end{cases}
\]

where \( \beta \) is any solution of

\[
   x^{2^{2\ell}} + x = (c + 1)^{2^{\ell}}.
\]

**Remarks**: Note that since \( t = k/\ell, k \) is odd by Corollary 2, \( \text{Tr}_{k/\ell}(k) c = 1 \). Hence \( w(c, 1) = 2^{k-1} + 2^{(k+\ell,k)-2}/2 \) if \( \text{Tr}_{k/\ell}(k) c = 1 \). The proof that \( w(1, 1) = w(c, 1) \) or \( 2^{k} - w(1, 1) \) in this case according as \( \text{Tr}(\beta + \beta 2^{\ell+1}) = 0 \) or \( 1 \) will not be given below, as it is entirely analogous to the proof given by Solomon [11] and Gold [5] for the case \( (\ell, k) = 1 \). If \( \text{Tr}_{k/\ell}(k) c = 1 \), a
theorem of McEliece [9] shows that the Eq. (1) has \(2^{(\ell,k)}\) solutions in \(GF(2^k)\), the solutions forming a coset of \(GF(2^k)\) with respect to \(GF(2^{(\ell,k)})\).

Hence, if \(\beta\) is any solution of (1), \(\beta + y\) is a solution for any \(y \in GF(2^{(\ell,k)})\). But

\[
\text{Tr}[(\beta + y) + (\beta + y)^{2^\ell+1}] = \text{Tr}(\beta + \beta^{2^\ell+1}) + \text{Tr}(y + y^{2^\ell+1}) + \text{Tr}(\beta^{2^\ell}y + \beta y^{2^\ell}).
\]

Since \(y \in GF(2^{(\ell,k)})\), \(y^{2^\ell} = y\), so \(\text{Tr}(y + y^{2^\ell+1}) = 0\), and

\[
\text{Tr}(\beta^{2^\ell}y + \beta y^{2^\ell}) = \text{Tr}(\beta^{2^\ell} + \beta)y.
\]

\[
= \text{Tr}(\ell,k)/1 [\text{Tr}_{k/(\ell,k)} (\beta^{2^\ell} + \beta)y]
\]

\[
= \text{Tr}(\ell,k)/1 [y \text{Tr}_{k/(\ell,k)} (\beta^{2^\ell} + \beta)]
\]

\[
= 0 \quad \text{(Ref. 1, pp. 118-119)}.
\]

since \(\text{Tr}_{k/(\ell,k)} (\beta^{2^\ell} + \beta) = (\text{Tr}_{k/(\ell,k)} \beta)^{2^\ell} + (\text{Tr}_{k/(\ell,k)} \beta) = 0\)

Hence, any two solutions to (1) have the same value of \(\text{Tr}(x + x^{2^\ell+1})\), so the weight is well-defined in (ii).

3. TRANSLATION OF THE PROBLEM

The remainder of this report will be devoted to the proofs of Theorem 1 and part (i) of Theorem 2. By our earlier remarks, it is sufficient to consider code words \(a \in A\) such that \(\psi(a) = (c, 1)\), where \(c \neq 0\). Then \(w(c, 1)\) is the number of \(x \in GF(2^k) - \{0\}\) such that \(g_a(x) = 1\), where

\[
g_a(x) = \text{Tr} cx + \text{Tr} x^{2^\ell+1}.
\]
Define $\rho(c)$ as the number of $x \in \text{GF}(2^k) - \{0\}$ such that

\[
\text{Tr } cx = 0 \\
\text{Tr } x^{2^\ell + 1} = 0
\]

hold simultaneously. Then, since each equation is satisfied separately by $2^{k-1} - 1$ elements of $\text{GF}(2^k) - \{0\}$, we have

\[(2) \quad w(c, 1) = 2^{k-1} - 1 - \rho(c).\]

Hence we can consider the function $\rho(c)$ in order to determine $w(c, 1)$.

Regard $\text{GF}(2^k)$ as a vector space over $\text{GF}(2)$, and let

$\{w_0, w_1, \ldots, w_{k-1}\}$ be a basis. Then any element $x \in \text{GF}(2^k)$ has a unique representation in the form $\sum x_i w_i$, where $x_i \in \text{GF}(2)$, $i = 0, 1, \ldots, k-1$. We associate the vector $x' = (x_0, x_1, \ldots, x_{k-1})$ with $x$. Then if $y = \sum y_i w_i$, we have

\[
\text{Tr } xy = \sum_{i=0}^{k-1} \sum_{j=0}^{k-1} x_i y_j \text{Tr}(w_i w_j)
\]

or

\[
\text{Tr } xy = x' T y,
\]

where $T = (t_{ij})$ is the $k \times k$ matrix over $\text{GF}(2)$ with $t_{ij} = \text{Tr } w_i w_j$. $T$ is non-singular, for otherwise there exists a non-null vector $\mathbf{c}'$ such that $\mathbf{c}' T = \mathbf{0}'$, the null vector. Then $\text{Tr } cx = 0$ for all $x \in \text{GF}(2^k)$, which implies $c = 0$, a contradiction.

The mapping $\sigma : x \mapsto x^{2^\ell}$ is an automorphism of $\text{GF}(2^k)$; hence there exists a non-singular $k \times k$ matrix $S$ over $\text{GF}(2)$ such that $\sigma(x) = Sx$.

(Take $S = (s_{ij})$, where $s_{ij} = s_{ji}'$ and $w_i^{2^\ell} = \sum_j s_{ij}' w_j$.) Thus we can write,
(3) \[ \text{Tr } xy^{2^\ell} = x' \text{ TS } y \]

for any \( x, y \in GF(2^k) \). In particular, if \( y = x^{2^\ell} \),

\[ \text{Tr } x^{2^\ell+1} = x' \text{ TS } x \]

is a quadratic form in \( x_0, x_1, \ldots, x_{k-1} \). Hence we see that \( \rho(c) \) is the number of non-null binary \( k \)-vectors \( \underline{x} \) such that the equations

\[
\begin{align*}
(4) \quad c' \text{ T } \underline{x} & = 0 \\
(5) \quad \underline{x}' \text{ TS } \underline{x} & = 0
\end{align*}
\]

hold simultaneously.

We now associate the elements \( x \in GF(2^k) - \{0\} \) with the points \( X \) of the finite projective geometry \( \text{PG}(k-1, 2) \) by the correspondence \( x \sim X \) if the coordinate vector of \( X \) is \( \underline{x}' = (x_0, x_1, \ldots, x_{k-1}) \), where \( x = \sum x_i w_i \). Eq. (4) then represents a hyperplane \( \Sigma_{k-2} \) and Eq. (5) a quadric \( Q_{k-1} \) in \( \text{PG}(k-1, 2) \). Hence the points \( X \) whose coordinate vectors satisfy (4) and (5) are the points of a quadric \( Q_{k-2} = Q_{k-1} \cap \Sigma_{k-2} \) in \( \Sigma_{k-2} \). Since \( T \) is non-singular, Eq. (4) establishes a one-one correspondence between the elements \( c \in GF(2^k) - \{0\} \) and the hyperplanes of \( \text{PG}(k-1, 2) \). We can thus determine the number of \( c \) such that \( \rho(c) = \rho \) by determining the number of hyperplanes \( \Sigma_{k-2} \) in \( \text{PG}(k-1, 2) \) such that \( |Q_{k-2}| = \rho \), where \( Q_{k-2} = Q_{k-1} \cap \Sigma_{k-2} \) and \( |Q_{k-2}| \) is the number of points of \( Q_{k-2} \). For this, we shall require some results on quadrics in \( \text{PG}(n, 2) \). Proofs not given below may be found in Bose [3] or Ray-Chaudhuri [10].

4. RESULTS ON QUADRICS IN \( \text{PG}(n, 2) \)

A quadric \( Q_n \) in \( \text{PG}(n, 2) \) consists of all points \( X \) whose coordinate vectors \( \underline{x}' = (x_0, x_1, \ldots, x_n) \) satisfy an equation
\[
\mathbf{x}' \mathbf{A} \mathbf{x} = 0,
\]

where \( \mathbf{A} = (a_{ij}) \) is an \((n + 1) \times (n + 1)\) matrix over GF(2). The rank of \( Q_n \) is defined to be the minimum number \( n + 1 - r \) of linear forms

\[
U_i = b_{i0} x_0 + b_{i1} x_1 + \ldots + b_{in} x_n, \quad i = 0, 1, \ldots, n+1-r
\]
such that \( \mathbf{x}' \mathbf{A} \mathbf{x} \) is expressible as a quadratic form in \( U_0, U_1, \ldots, U_{n+1-r} \).

The rank of \( Q_n \) is related to the rank of the symmetric matrix \( \mathbf{A} + \mathbf{A}' \) by

\[
\text{rank } (\mathbf{A} + \mathbf{A}') = 2\left[ \frac{1}{2} \text{rank } Q_n \right],
\]

where \([x] \) is the greatest integer not exceeding \( x \).

If \( r = 0 \), i.e., if \( \text{rank } Q_n = n + 1 \), \( Q_n \) is a non-degenerate quadric. If \( r > 0 \), \( Q_n \) is degenerate of order \( r \). In this case, \( Q_n \) is called a cone of order \( r \). We shall find it convenient to regard a non-degenerate quadric as a cone of order zero.

If \( n \) is even, non-degenerate quadrics are of one type. These contain \( 2^n - 1 \) points and flat spaces of dimension \((n-2)/2\). If \( n \) is odd, there are two types of non-degenerate quadrics: hyperbolic (ruled) quadrics contain \( 2^n + 2^{(n-1)/2} \) points and flat spaces of dimension \((n-1)/2\); elliptic (unruled) quadrics contain \( 2^n - 2^{(n-1)/2} - 1 \) points and flat spaces of dimension \((n-3)/2\). (By convention, a flat space of dimension \(-1\) is empty.)

If \( Q_n \) is a cone of order \( r \), there exists a unique \((r-1)\)-flat \( \Sigma_{r-1} \), called the vertex of \( Q_n \), such that the points of \( Q_n \) are those of the lines joining points of \( \Sigma_{r-1} \) to points of \( Q_{n-r} \), where \( Q_{n-r} \) is a non-degenerate quadric in \( n - r \) dimensions obtained by intersecting \( Q_n \) with any \((n-r)\)-flat \( \Sigma_{n-r} \) which is skew to \( \Sigma_{r-1} \). If \( n - r \) is odd, \( Q_n \) is an
elliptic or hyperbolic cone according as \( Q_{n-r} \) is an elliptic or hyperbolic quadric. The number \(|Q_n|\) of points on \( Q_n \) is given by

\[
|Q_n| = 2^r - 1 + 2^r|Q_{n-r}|.
\]

We therefore have

\[
|Q_n| = \begin{cases} 
2^n - 1 & \text{if } n - r \text{ even}, \\
2^n + 2^{(n-r-1)/2} - 1 & \text{if } n - r \text{ odd, } Q_{n-r} \text{ hyperbolic}, \\
2^n - 2^{(n-r-1)/2} - 1 & \text{if } n - r \text{ odd, } Q_{n-r} \text{ elliptic}.
\end{cases}
\]  

A point \( B \) of \( PG(n, 2) \) with coordinate vector \( b \) is said to be irregular (regular) with respect to \( Q_n \) if \( b'(A + A') \) is null (non-null). The set of irregular points clearly form a flat space, called the nucleus of polarity of \( Q_n \). If \( Q_n \) is non-degenerate, every point is regular if \( n \) is odd. If \( n \) is even, the nucleus of polarity consists of a single point \( B \in Q_n \). More generally, if \( Q_n \) is a cone of order \( r \), the nucleus of polarity is the vertex \( \Sigma_{r-1} \) if \( n - r \) is odd. If \( n - r \) is even, the nucleus of polarity is the \( r \)-flat \( \Sigma_r \) containing \( \Sigma_{r-1} \) and \( B \), where \( B \) is the nucleus of polarity of the non-degenerate quadric \( Q_{n-r} \). In this case, \( \Sigma_r \cap Q_n = \Sigma_{r-1} \).

If \( Q_n \) is non-degenerate, \( n \) is even, and \( \Sigma_{n-1} \) is any hyperplane of \( PG(n, 2) \), then the quadric \( Q_{n-1} = Q_n \cap \Sigma_{n-1} \) is non-degenerate if and only if \( B \in Q_{n-1} \), where \( B \) is the nucleus of polarity of \( Q_n \). If \( B \in \Sigma_{n-1} \), \( Q_{n-1} \) is a cone of order one. We use these results to prove

**Lemma 2:** Let \( Q_n \) be a non-degenerate quadric in \( PG(n, 2) \), \( n \) even, and let \( B \) be the nucleus of polarity of \( Q_n \). Let \( \Sigma_{n-1} \) be a hyperplane, and define \( Q_{n-1} = Q_n \cap \Sigma_{n-1} \). Then if \( B \in \Sigma_{n-1} \),
1. \( Q_{n-1} \) is a cone of order one; if \( B \not\subset \Sigma_{n-1} \), then either

2. \( Q_{n-1} \) is a non-degenerate hyperbolic quadric,

or

3. \( Q_{n-1} \) is a non-degenerate elliptic quadric.

The numbers \( N_t, t = 1, 2, 3, \) of hyperplanes \( \Sigma_{n-1} \) for which \( Q_{n-1} \) is of type \( t \) are

\[
N_1 = 2^n - 1,
N_2 = 2^{n-1} + 2^{(n-2)/2},
N_3 = 2^{n-1} - 2^{(n-2)/2}.
\]

**Proof:** The first part is simply a restatement of the above results. To determine the \( N_t \), we count the number of pairs \((P, \Sigma_{n-1})\) where \( P \) is a point of \( Q_n \) and \( \Sigma_{n-1} \) is a hyperplane containing \( P \). Since each point of \( PG(n-1, 2) \) is contained in \( 2^n - 1 \) hyperplanes and there are \( 2^n - 1 \) points on \( Q_n \) by (6), the number of such pairs is \((2^n-1)^2\). Counting these pairs in a second way, using (6), we obtain

\[
(2^n-1)^2 = N_1(2^{n-1}-1) + N_2(2^{n-1}+2^{(n-2)/2}-1) + N_3(2^{n-1}-2^{(n-2)/2}-1)
\]

or

\[
(2^n-1)^2 = \left( N_1 + N_2 + N_3 \right)(2^{n-1}-1) + 2^{(n-2)/2} (N_2 - N_3).
\]

Since \( N_1 + N_2 + N_3 = 2^{n+1} - 1 \), the total number of hyperplanes, and \( N_1 = 2^n - 1 \), the number of hyperplanes containing \( B \), we have

\[
N_2 + N_3 = 2^n,
\]

and

\[
N_2 - N_3 = 2^{n/2}.
\]
Solving these equations for $N_2, N_3$, we have

**Lemma 3**: Let $Q_n$ be a cone of order $r$ in $\text{PG}(n, 2)$, where $n-r$ is even. Let $\Sigma_r$ be the nucleus of polarity of $Q_n$ and $\Sigma_{r-1} = \Sigma_r \cap Q_n$ the vertex. Let $\Sigma_{n-1}$ be a hyperplane and define $Q_{n-1} = Q_n \cap \Sigma_{n-1}$.

Then if $\Sigma_{r-1} \notin \Sigma_{n-1}$,

0. $Q_{n-1}$ is a cone of order $r - 1$;

if $\Sigma_r \subset \Sigma_{n-1}$,

1. $Q_{n-1}$ is a cone of order $r + 1$;

if $\Sigma_{r-1} \subset \Sigma_{n-1}$ but $\Sigma_r \notin \Sigma_{n-1}$; then either

2. $Q_{n-1}$ is a hyperbolic cone of order $r$,

or

3. $Q_{n-1}$ is an elliptic cone of order $r$.

The number $N_t$, $t = 0, 1, 2, 3$, of hyperplanes $\Sigma_{n-1}$ for which $Q_{n-1}$ is of type $t$ is

$$
N_0 = 2^{n+1} - 2^{n-r+1},
$$

$$
N_1 = 2^{n-r} - 1,
$$

$$
N_2 = 2^{n-r-1} + 2(n-r-2)/2,
$$

$$
N_3 = 2^{n-r-1} - 2(n-r-2)/2.
$$

**Proof**: If $\Sigma_{r-1} \notin \Sigma_{n-1}$, then $\Sigma_{n-1}$ contains an $(n-r)$-flat $\Sigma_{n-r}$ skew to $\Sigma_{r-1}$. The quadric $Q_{n-r} = Q_n \cap \Sigma_{n-r}$ is non-degenerate in $\Sigma_{n-r}$, and $Q_{n-1}$ clearly consists of all points on the lines joining points of $Q_{n-r}$ to points of $\Sigma_{r-2} = \Sigma_{r-1} \cap \Sigma_{n-1}$. Hence, $Q_{n-1}$ is a cone of order $r - 1$ with vertex $\Sigma_{r-2}$.

Suppose now $\Sigma_{r-1} \subset \Sigma_{n-1}$. Let $\Sigma_{n-r}$ be a fixed $(n-r)$-flat skew to $\Sigma_{r-1}$, and let $Q_{n-r} = Q_n \cap \Sigma_{n-r}$. There is a one-one correspondence between
hyperplanes $\Sigma_{n-1}$ containing $\Sigma_{r-1}$ and $(n-r)$-flats $\Sigma_{n-r-1}$ of $\Sigma_{n-r}$, such that $\Sigma_{n-r-1} \sim \Sigma_{n-1}$ if and only if $\Sigma_{n-r-1} = \Sigma_{n-1} \cap \Sigma_{n-r}$. Since $Q_{n-r}$ is non-degenerate, we can apply Lemma 2 to obtain the numbers $N_1, N_2, N_3$ of $n$-r-flat $\Sigma_{n-r-1}$ in $\Sigma_{n-r}$ for which $Q_{n-r-1} = Q_{n-r} \cap \Sigma_{n-r-1}$ is a cone of order one, a non-degenerate hyperbolic quadric, and a non-degenerate elliptic quadric, respectively. But if $\Sigma_{n-1} \sim \Sigma_{n-r-1}$, and $Q_{n-r-1}$ is a cone of order $s$ in $\Sigma_{n-r}$, then $Q_{n-1}$ is a cone of order $r+s$ in $\Sigma_{n-1}$. The vertex $\Sigma_{r+s-1}$ of $Q_{n-1}$ is the join of $\Sigma_{r}$ and $\Sigma_{s}$, where $\Sigma_{s}$ is the vertex of $Q_{n-r-1}$. The proof is completed by noting that if $B$ is the nucleus of polarity of $Q_{n-r-1}$, then $B = \Sigma_{r} \cap \Sigma_{n-r}$, and hence $B \in \Sigma_{n-r-1}$ if and only if $\Sigma_{r} \subset \Sigma_{n-1}$.

**COROLLARY 3:** Let $M(\rho)$ be the number of hyperplanes $\Sigma_{n-1}$ which intersect $Q_{n}$ in exactly $\rho$ points. Then we have

<table>
<thead>
<tr>
<th>$\rho$</th>
<th>$M(\rho)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$2^{n-1} - 1$</td>
<td>$2^{n+1} - 2^{n-r} - 1$</td>
</tr>
<tr>
<td>$2^{n-1} + 2^{(n+r-2)/2} - 1$</td>
<td>$2^{n-r-1} + 2^{(n-r-2)/2}$</td>
</tr>
<tr>
<td>$2^{n-1} - 2^{(n+r-2)/2} - 1$</td>
<td>$2^{n-r-1} - 2^{(n-r-2)/2}$</td>
</tr>
</tbody>
</table>

**Proof:** Apply (6) with $n-1$ replacing $n$ and note that the quadrics of types 0 and 1 have the same number of points.

5. **PROOF OF THEOREMS 1 AND 2**

We now consider the quadric $Q_{k-1}$ in $PG(k-1, 2)$ with equation

$$x' TS x = 0.$$
The points of $Q_{k-1}$, we recall, correspond to the elements $x \in GF(2^k) - \{0\}$ for which $\text{Tr} x^{2^{k-1}+1} = 0$. Then it is clear that $Q_{k-1}$ has $2^{k-1} - 1$ points, and by comparison with Eq. (6), we see that $Q_{k-1}$ is a cone of order $r \geq 0$, where $k - 1 - r$ is even. The previous corollary then shows that the function $\rho(c)$ is three-valued. In order to specify the values and the number of $c$'s mapped into each value, we must determine the order $r$ of $Q_{k-1}$.

Since $k - 1 - r$ is even, the nucleus of polarity of $Q_{k-1}$ is an $r$-flat $\Sigma_r$ intersecting $Q_{k-1}$ in the vertex $\Sigma_{r-1}$. We have

**Lemma 4**: The order of $Q_{k-1}$ is $r = (\ell, k) - 1$. The points of the nucleus of polarity $\Sigma_{(\ell,k)-1}$ correspond to the elements of $GF(2^{(\ell,k)}) - \{0\}$. The points of the vertex $\Sigma_{(\ell,k)-2}$ correspond to the elements $b$ of $GF(2^{(\ell,k)}) - \{0\}$ for which $\text{Tr} b = 0$.

**Proof**: The points $B$ of $\Sigma_r$ are those whose coordinate vectors $b$ satisfy

$$b'(TS + (TS)') = 0',$$

where $0'$ denotes the null vector. Equivalently, $B \in \Sigma_r$ if and only if

$$b' TS x = x' TS b$$

for all binary $k$-vectors $x$. Using Eq. (2), (7) holds if and only if, for all $x \in GF(2^k)$,

$$\text{Tr} b x^{2^\ell} = \text{Tr} b^{2^\ell} x$$

or

$$\text{Tr} b^{2^{-\ell}} x = \text{Tr} b^{2^\ell} x.$$
Thus \( b^{2-\ell} = b^{2\ell} \), or \( b^{2^2\ell} = b \). Hence, if \( e \) is the order of \( b \), then \( e \mid 2^\ell - 1 \). Since \( e \mid 2^k - 1 \), \( e \) divides \( (2^2\ell - 1, 2^k - 1) = 2^{(2\ell, k)} - 1 = 2^{(\ell, k)} - 1 \) for \( \ell \in L(k) \). Thus \( b \in GF(2^{(\ell, k)}) \). Conversely, if \( b \in GF(2^{(\ell, k)}) \), \( b^{2^\ell} = b \). Hence \( \Sigma_r \) contains \( 2^{(\ell, k)} - 1 \) points, and therefore \( r = (\ell, k) - 1 \).

The points of the vertex \( \Sigma(\ell,k) - 2 \) thus correspond to the elements \( b \) of \( GF(2^{(\ell, k)}) - \{0\} \) such that \( \text{Tr} b^{2^\ell + 1} = 0 \). But

\[
2^\ell + 1 = \left( \frac{2^\ell - 1}{2^{(\ell, k)} - 1} \right) (2^{(\ell, k)} - 1) + 2,
\]

so that \( b^{2^\ell + 1} = b^2 \), and \( \text{Tr} b^{2^\ell + 1} = \text{Tr} b^2 = \text{Tr} b \). Thus \( B \in \Sigma(\ell,k) - 2 \) if and only if \( b \in GF(2^{(\ell, k)}) - \{0\} \) and \( \text{Tr} b = 0 \).

On substituting the values \( n = k - 1 \) and \( r = (\ell, k) - 1 \) into the expressions for \( \rho \) and \( M(\rho) \) of the corollary, and using Eq. (2), we obtain the weight distribution of the words \( a \in A \) for which \( \psi(a) = (c, 1) \), \( c \neq 0 \):

<table>
<thead>
<tr>
<th>Weight</th>
<th>No. of Code Words</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. ( 2^{k-1} )</td>
<td>( 2^k - 2^{k-(\ell, k)} - 1 )</td>
</tr>
<tr>
<td>2. ( 2^{k-1} - \frac{2(k+(\ell,k)-2)}{2} )</td>
<td>( 2^{k-(\ell,k)} - 1 + 2^{(k-(\ell,k)-2)}/2 )</td>
</tr>
<tr>
<td>3. ( 2^{k-1} + \frac{2(k+(\ell,k)-2)}{2} )</td>
<td>( 2^{k-(\ell,k)} - 1 - 2^{(k-(\ell,k)-2)}/2 )</td>
</tr>
</tbody>
</table>

We obtain the weight distribution of Theorem 1 by multiplying the numbers in the right-hand column by \( 2^k - 1 \) to include all cyclic shifts of the type \((c, 1)\) words, and adding \( 2(2^k-1) \) to the number so obtained for the weight.
words to include the words of type \((c, 0)\) and \((0, d)\). This completes the proof of Theorem 1.

Returning now to the words of type \((c, 1)\), where \(c \neq 0\), we note that the words of weight \(2^{k-1} + 2^{(k+(\ell,k)-2)/2}\) are those for which \(Q_{k-2}\) is of type 2 or 3 in Lemma 3, where \(Q_{k-2} = Q_{k-1} \cap \Sigma_{k-2}\) and \(\Sigma_{k-2}\) is the hyperplane with equation \(c' \mathbf{T} \mathbf{x} = 0\). But \(Q_{k-2}\) is of type 2 or 3 if and only if \(\Sigma_{k-2} \cap \Sigma(\ell,k)-1 = \Sigma(\ell,k)-2\). Thus \(w(c, 1) \neq 2^{k-1}\) if and only if, for all \(x \in \text{GF}(2^{(\ell,k)})\),

\[
\text{Tr} cx = \begin{cases} 
0 & \text{Tr } x = 0, \\
1 & \text{Tr } x = 1,
\end{cases}
\]

i.e., if and only if \(\text{Tr}(c+1)x = 0\) for all \(x \in \text{GF}(2^{(\ell,k)})\).

But

\[
\text{Tr}(c+1)x = \text{Tr}(\ell,k)/1 [\text{Tr}(\ell,k)/(\ell,k) (c+1)x]
\]

\[
= \text{Tr}(\ell,k)/1 [x \text{ Tr}(\ell,k)/(\ell,k) (c+1)]
\]

for \(x \in \text{GF}(2^{(\ell,k)})\), \([1, \text{pp.}118-119]\). Hence \(\text{Tr}(c+1)x = 0\) for all \(x \in \text{GF}(2^{(\ell,k)})\) if and only if \(\text{Tr}(\ell,k)/(\ell,k) (c+1) = 0\). Since \(k/(\ell, k)\) is odd by Corollary 2, \(\text{Tr}(\ell,k)/(\ell,k) = 1\). Hence \(w(c, 1) \neq 2^{k-1}\) if and only if \(\text{Tr}(\ell,k)/(\ell,k) = 1\). This completes the proof of part (i) of Theorem 2.
